ERYTHEMA MULTIFORME - ETIOPATHOGENIC, CLINICAL AND THERAPEUTIC ASPECTS (Abstract): **Aim**: To present the epidemiological, etiopathogenic, clinical and therapeutic aspects in *Erythema multiforme* (EM). **Material and methods:** This is a 3-year retrospective study based on medical records of patients with EM admitted to the Dermatology Clinic. Forty patients were included in this study. The obtained data allowed the classification of patients according to their distribution by sex, age group, area of residence, etiology, clinical aspects, and type of administered treatment. **Results:** The prevalence of EM during the 3 study years was 0.4%. EM prevailed among the rural population, more frequently in women. The minimum age at which EM was diagnosed was 12 years and maximum age 78 years, with a peak incidence between 20-40 years old (37.5% cases). In 42.50% of the cases EM was drug-induced, and in 17.50% of cases it was caused by infection with herpes simplex virus (HSV). There were 18 cases of erythemotous–papular EM (45%), 14 cases of erythematous - vesiculobullous EM (35%) and 8 cases of recurrent EM (20%). All patients received treatment with antihistamines and nonspecific desensitizing agents. Systemic corticotherapy was used in 22 cases. Three patients received treatment with acyclovir. **Conclusions:** *Erythema multiforme* is a rare skin condition, easily diagnosed based on its characteristic clinical appearance, but remains a challenge for the physician in terms of establishing its causal agent. **Keywords:** ERYTHEMA MULTIFORME, STEVENS-JOHNSON SYNDROME, LYELL'S SYNDROME.

Polymorphic erythema or erythema multiform is part of the group of cutaneous – mucosal hypersensitivity reactions, a disease with multiple etiologies, with typical cutaneous and/or mucous clinical manifestations, the episode being self-limited, sometimes recurrent (1). The etiology and pathogenesis are not fully elucidated yet. Its various clinical manifestations range from the simple papular form (the characteristic lesions being erythematous papules, acral in distribution and symmetrical), and erythematous-vesiculobullous form (lesions are erythematous plaques with a vesicle or bulla arranged centrally that can develop a pathognomonic "target-like" or "cockade " appearance) to the severe bullous form (severe damage to the mucous membranes,

the damage to the skin membranes varying in extent and severity). The papular form is also called *Erythema multiforme* minor, and the other two forms, erythematous – vesiculobullous and severe bullous, are included into the *Erythema multiforme* major. Among the precipitating factors are medications and infectious agents. Recurrence may be common, most patients experiencing 1-2 recurrences per year. This is explained by the fact that in some cases EM can be associated with a persistent antigenic stimulation leading to repeated manifestations of the disease. In the medical literature EM is often confused with Stevens – Johnson syndrome (SJS) and Lyell's syndrome (toxic epidermal necrolysis = TEN). It was only in 1993 that a consensus regarding the classification of these three conditions was reached: SJS was separated from the EM and included in TEN, SJS and TEN being considered variants of the same disease, different only by the degree of severity (<10% of body surface area affected corresponds to SJS, and > 30% to TEN) (2).

The not completely understood pathogenesis and multiple etiology are other factors that make the knowledge of this disease to be of particular interest in medical practice.

MATERIAL AND METHODS

For this retrospective, open-label study we studied a group of patients admitted with a diagnosis of *Erythema multiforme* to the Dermatology Clinic of the Iasi "St. Spiridon" Emergency Hospital in the interval January 1, 2006 – December 31, 2008. The aim was to gather data on clinical manifestations, investigation methods and therapies used. Included in the study were 40 patients (some patients with multiple admissions during the 3 study years). The data obtained allowed the classification of patients according to their distribution by sex, age group, area of residence, etiology, clinical aspects, association with other diseases, type of administered treatment and its efficiency. To interpret the data different statistical concepts were used: arithmetic mean, percentage distribution.

RESULTS

During the interval January 1, 2006 – December 31, 2008 a total of 11,204 admissions (of which 5,311 day admissions) were recorded. Of these, 45 admissions were for the diagnosis and treatment of erythema multiforme, corresponding to a number of 40 patients. The prevalence of *Erythema multiforme* over the 3-year study period was 0.4%.

The distribution by area of residence revealed that EM was more common among the rural population (65% vs. 35%), corresponding to an urban/rural patient ratio of 1: 1.86.

There was a higher rate of EM among female patients, the male: female ratio being 1: 1.35 (fig. 1). According to the literature men are more frequently affected than women, more precisely with a male/female ratio ranging from 3:2 to 2:1.

The minimum age at which the occurrence of EM was recorded was 12 years and the maximum age 78 years. Our data were in agreement with literature data according to which all ages are affected, with a peak incidence between the 2nd and 4th decade of life, about 20% of patients being children and adolescents. In our study the peak incidence was indeed between 20-40 years, 37.5% of cases, but the highest percentage of all cases, 27.5%, was recorded in the 30 - 40 year age group. Fifteen percent of our patients were children and adolescents aged

less than 20 years, close to the 20% mentioned in the literature. However we found a significant percentage of cases in patients older than 50 years (32.5%), although EM is considered rare under the age of 3 and above 50 years (fig. 2).

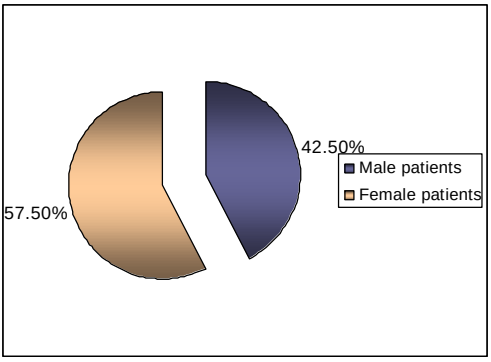

Fig. 1. Distribution of patients by gender

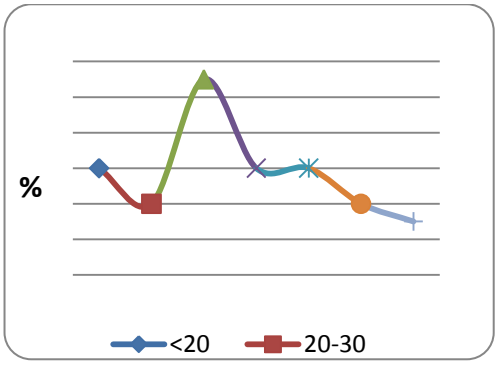

Fig. 2. Distribution by age groups

The onset was sudden in most cases, with rapid, progressive extension of lesions. Eight of the 40 patients had prodromes with constitutional symptoms (moderate fever or subfebrility, headache, asthenia, nausea, vomiting, etc.), some similar to a viral syndrome prodrome. As a result of this, some patients decided to self-medicate to relive these symptoms, making it difficult to differentiate the possible etiology of EM in these cases.

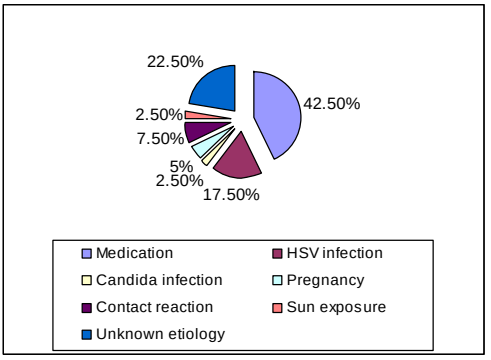

Fig. 3. Etiology of EM

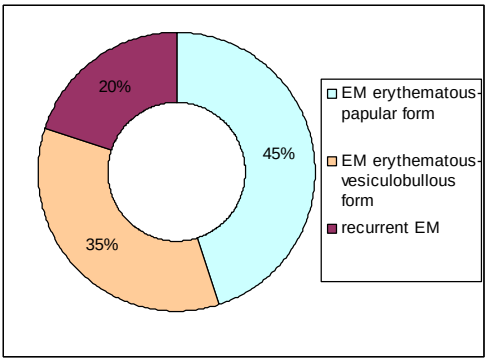

Fig. 4. Clinical forms of EM

As to the medication administered before the disease onset, of the 45 admissions 17 patients confirmed taking various drugs, including antibiotics, NSAIDs, antipyretics, combinations of NSAIDs and other compounds (acetylsalicylic acid in combination with paracetamol and caffeine), sedatives, estrogen receptor modulator, antifungal agents. In several cases the patients took more medicines simultaneously, making it more difficult to establish the one responsible for EM.

Another factor considered to be responsible for the occurrence of EM is herpes simplex virus (HSV) infection. From patient history we found that 7 patients showed signs of labial herpes simplex infection. Of these 7 patients, 4 were diag-

nosed with recurrent EM, 3 patients presenting the erythematous-vesiculobullous form and 1 the erythematous-papular form. These 4 patients presented signs of EM for 8 months to 13 years. Bacterial and fungal infections were also detected: due to beta hemolytic streptococcus (2 cases of streptococcal pharyngitis), candida infection (4 cases of oral candidiasis) infection with dermatophytes (*tinea pedis* = 4 cases, onychomycosis = 1 case). Other possible causes of EM resulting from patient history were: solvents, detergents and other irritant solutions, printing ink, sun exposure, pregnancy (fig. 3).

Of the total of 45 admissions, 2 patients had a check-up admission one month after the first presentation to the clinic, while other 2 patients with recurrent EM had 3 and 2 admissions, respectively, for distinct EM episodes, thus totaling 40 EM patients with 43 admissions. Twenty-two patients presented manifestations of EM erythematous-papular form, while 21 patients EM erythematous-vesiculobullous form. Of these, 8 patients were diagnosed with recurrent EM. One of the 2 patients with multiple admissions had 1 episode of erythematous- papular EM and 2 episodes of erythematous-vesiculobullous EM, while the other patient had 1 episode of EM erythematous-papular form and 1 episode of erythematous-vesiculobullous EM. Thus of the total of 43 admissions, 18 cases had erythematous- papular EM, 14 cases erythematous-vesiculobullous EM and 8 cases recurrent EM, totaling 40 patients (fig. 4). Of the 8 patients with recurrent EM 4 had symptoms of erythematous-papular type and the other 4 of erythematous-vesiculobullous type. In 4 cases (3 with erythematous-vesiculobullous form and 1 case with erythematous-papular form) the etiology was herpetic, in one case a contact reaction and in the other 3 cases the causal factor was not detected. Special attention deserved the 2 EM pregnant women (pregnancy weeks 28 and 31, respectively). One of these women was diagnosed with EM erythematous-papular form, and other with EM erythematous-vesiculobullous form. No other causal factor other than pregnancy could be related to the occurrence of this disease.

Typical acral distribution (fig. 5, 6) was present in 42 of the 43 cases, oral mucosa was affected in 7 cases (fig. 7), lesions on the trunk were present in 9 cases and genital lesions were found in 3 cases.

Fig. 5. Target-like lesions on palms

Fig. 6. Target-like lesions on soles

The lesions occurred progressively, symmetrically, with centripetal spreading, which is consistent with literature data. Acral involvement, another important feature in the diagnosis of EM, was present in 98% of cases; most commonly affected being the back of the hands, palms and soles in 70, 59 and 40% of the cases, respectively.

Pruritus was present in 12 cases, and pain in 6 cases, of which 3 with oral and genital mucosal involvement and 3 with the erythematous-vesiculobullous form. Burning sensation was present in 4 cases.

Twenty-two cases of minor EM and 21 cases of major EM were recorded.

Thirty-one (77.50%) of the 40 study patients presented associated diseases, the most common being *tinea pedis*, oral candidiasis, chronic venous insufficiency, essential hypertension, dyslipidemia.

All patients received treatment with antihistamines and nonspecific desensitizing agents (Ca + vitamin D_3, vitamin C). These were used as adjuvant agents in the treatment of EM which in this study consisted of topical therapy (dermatocorticoids) and systemic therapy (systemic corticosteroids). Systemic corticosteroid therapy was used in 9 cases with EM erythematous-papular form and in 13 cases with erythematous-vesiculobullous EM. The recommended dose was generally 0.5-1 mg/kg/day of prednisone or equivalent dose of methylprednisolone for a short period of time (10 days). Also used were: betamethasone (6 cases), dexamethasone (3 cases) and hydrocortisone hemisuccinate (5 cases). Treatment with acyclovir was administered in 3 cases of recurrent EM of herpetic etiology.

All 43 cases had a favorable outcome, the lesions disappearing after treatment. Of the eight cases of recurrent EM one patient had six episodes of EM over 8 months. In the other cases the episodes occurred about once a year. Adherence to treatment was good, given that the treatment was short-term, and the prognosis was favorable in all cases.

Fig. 7. Oral mucosal involvement

DISCUSSION

In the present study EM had some features consistent with literature data (incidence of less than 1%, more frequent in second to fourth decades of life, onset with prodromal symptoms in 20% of cases, favorable, self-limited course).

The 6 cases in children and adolescents under 20 years of age accounted for 15% of the cases, close to the percentage of 20% reported by other authors (3). A significant percentage (32.5%) of patients was diagnosed at an age older than 50 years, although EM is considered rare under the age of 3 and over 50 years.

Regarding the etiology of EM the drug factor was involved in a considerable percentage of cases, 42.50% (most commonly involved being the antibiotics – especially amoxicillin, and NSAIDs). According to several authors the drugs involved in the etiology of this disease are primarily the sulfonamides, followed by anticonvulsants

and other types of medication (antibiotics, antifungal agents, NSAIDs, and others) (4, 5, 6, 7, 8). In the literature there are numerous case reports of EM due to the use of drugs, but there is no test that can accurately demonstrate the association between a single case and a specific drug. In our study patients various drugs have been were administered concomitantly, making it difficult to differentiate the possible etiology of EM in these cases.

HSV infection, another reported etiologic factor associated with EM minor (9, 10) was found in only 7 cases, being associated with only one case of EM minor the erythematous–papular form. Other infectious causes are the infections with streptococcus, mycoplasma, dermatophytes, cytomegalovirus (CMV) and Epstein Barr virus (EBV) (11, 12, 13). Virus-drug interactions have been reported as a trigger factor for the occurrence of EM, these including CMV infection and terbinafine treatment (14) and EBV infection and amoxicillin treatment (15). In the present study the presence of beta-hemolytic streptococcal infection (2 cases of streptococcal pharyngitis), candida infection (4 cases of oral candidiasis), dermatophyte infection (*tinea pedis* 4 cases, 1 case of onychomycosis) was detected.

The clinical manifestations were key to diagnosis, cases of EM erythematous-papular form and erythematous- papulovesicular form, recurrent EM and EM during pregnancy being recorded. Physical examination was sufficient to establish the diagnosis in all cases. In EM major the mucous membranes can be also involved: oral mucosa showing *bullae* that progress to painful erosions, genital mucosa by vulvitis or balanitis, and conjunctival mucosa by conjunctivitis or corneal ulceration. These can lead to complications such as dehydration and fluid and electrolyte imbalances, secondary bacterial infections, ocular complications (corneal ulcers, anterior uveitis, corneal opacities, etc.). Scars (especially on mucosal lesions), and strictures (esophageal, lower respiratory tract, urethral, vaginal, anal) are less common. Oral mucosal involvement was found in 16% of patients and genital mucosal involvement in 7% without complications.

For the diagnosis of EM laboratory tests are not highly specific. However, the results of routine investigations were consistent with the data in the literature, revealing inflammatory syndrome, mild leukocytosis, mild anemia, and hypereosinophilia in most cases.

With regard to the treatment of EM, mainly used was corticoid therapy, both systemic and topical. Although the literature states that its use is controversial being even contraindicated in the mild forms of disease and the most severe may increase the risk of complications without improving the prognosis, in this study the use of corticosteroids did not lead to complications, with favorable outcome in all cases. Treatment with acyclovir was administered in 3 cases of recurrent EM of herpetic etiology.

CONCLUSIONS

Erythema multiforme is a rare skin condition, easily diagnosed based on the characteristic clinical appearance, but remains a challenge for the physician with respect to establishing the causal agent, in the literature most cases being considered idiopathic. In the present study the drug factor was incriminated in almost half of the cases (42.50%), but we cannot say with certainty that there is a cause- effect relationship

between administered drug and disease occurrence. The presence of prodromal symptoms in a significant number of cases (20%) and self-medication in these cases before presentation to the doctor make impossible the accurate detection of the trigger factor. The therapeutic goals were EM cure and prophylaxis for the prevention of recurrences. In cases of EM major interdisciplinary collaboration is important as ophthalmology, ENT, gynecology, urology, gastroenterology consultations may be required.

PATIENT FIRST: DIRECT ACTING ANTIVIRAL (DAA) THERAPY IN REAL WORLD HCV COMPENSATED CIRRHOSIS (Abstract): **Aim:** Given the effectiveness of direct acting antiviral (DAA) therapy in patients with chronic hepatitis C virus (HCV) infection, we aimed to describe the demographic, clinical and biological characteristics of our patients who received treatment with direct acting antivirals during December 2015-October 2016 and September 2017-January 2018. **Material and Methods:** We performed a prospective study of 186 patients with chronic hepatitis C who have undergone treatment with paritaprevir/ombitasvir/ritonavir and dasabuvir with or without ribavirin during December 2015 - October 2016 (group 1) and September 2017 - January 2018 (group 2). The inclusion and exclusion criteria were established according to the national protocol. Demographic, clinical and biological data were recorded before starting treatment. All patients underwent upper gastrointestinal endoscopy and abdominal ultrasound. The determination of HCV genotypes and subtypes was realized by the Abbott RealTime HCV assay. The presence of mild or advanced fibrosis, cirrhosis, the viral necro inflammatory activity and the presence of nonalcoholic steatohepatitis (NASH) were assessed by FibroMax non-invasive liver tests: ActiTest, FibroTest and NashTest. **Results:** The mean age was 58.7 years for the first group and 59.6 for the second group, with the predominance of female gender in both cases. Genotype 1b was present exclusively in the first group. Median HCV RNA at baseline was 1 264 123.180 IU/mL for the first group and 1 678 718.97 IU/mL for the second group. No patients were HBV or HIV co-infected. Most patients were naive to interferon therapy. The comorbidity rate was increased in both groups: 28.82% *vs.* 49.3% had cardiovascular diseases, 23.41% *vs.* 14.66% had diabetes mellitus (with or without insulin requirement), 2.7% *vs.* 10.6% had thyroid dysfunction, 1.8% *vs.* 0% had dermatological disease, 0.9% *vs.* 5.33% had psychiatric disorders, 1.8% *vs.* 1.33% had a history of cured neoplasm, 1.8% *vs.* 2.66% had pulmonary diseases and 0.9% *vs.* 1.33% had hematological diseases. No patient had a history of treated hepatocellular carcinoma. In both groups, the maximum number of drugs administered simultaneously with the antiviral therapy was 4. The necro inflammatory activity assessed by ActiTest highlights a high rate for severe activity for both groups - 66.6%. The prevalence of concomitant NASH assessed by NashTest (N2-severe inflammation) was 50% in group 1 and 53.3% in group 2. There were slight differences between the two groups in terms of biological constants, but without any statistical significance. **Conclusions:** The partial results of our study show a higher prevalence of HCV infection among people born

between 1946 and 1964 (baby boom generation), especially women. In this geographical area, genotype 1b was found exclusively. Most patients, naïve to interferon therapy, associate numerous comorbidities and simultaneous treatments that may decrease adherence to therapy due to the possibility of significant drug-drug interactions, requiring optimal therapeutic management and close monitoring. **Keywords**: DIRECT ACTING ANTIVIRALS, HEPATITIS C VIRUS INFECTION, COMORBIDITIES.

Hepatitis C virus (HCV), discovered in 1989, is an enveloped positive-sense single-stranded RNA virus recognized as the main causative agent of chronic liver disease, cirrhosis and hepatocellular carcinoma (1, 2). The global prevalence of HCV estimated by WHO is approximately 2.5% (185 million people), with a higher rate in Africa and Asia compared to North America, Europe and Australia (1,3,4). HCV related liver failure is the main indication of liver transplantation in the United States, Western Europe and Japan (2,5,6).

In the presence of humoral and cellular immune response directed against viral proteins, 70-100% of patients remain HCV-RNA positive secondary to acute infection due to the immune system's ability to circumvent the virus (7,8,9). Heterogeneity of HCV genome arises as a result of DNA-dependent RNA polymerase (NS5B) that causes viral replication to mis-incorporate ribonucleotides with a substitution rate of about one million more than the replacement rate for the human genome (10).

Most patients are asymptomatic or have nonspecific manifestations: fatigue, myalgia, arthralgia and weight loss. Evolution is slowly progressive to liver cirrhosis, hepatocarcinoma or death (9, 11).

Interferon (INF) has been the standard treatment for about 25 years. It was first approved in HCV patients in 1991, although its antiviral activity was first described in 1957. Under interferon monotherapy, the SVR rate increased from 5 to 20% and up to 40-80% with pegylated interferon plus ribavirin (12).

Knowing the replicative cycle of hepatitis C virus, the role of structural and non-structural proteins and their localization in the cell allowed the discovery of compounds with specific antiviral activity.

The main targets are the NS5A replication complex (daclatasvir, ledipasvir, ombitasvir, elbasvir, velpatasvir), the NS5B polymerase (sofosbuvir, dasabuvir) and the NS3/4A protease (simeprevir, paritaprevir, asunaprevir, grazoprevir) (10,13).

The main goal of antiviral therapy is to obtain suppression of the virus replication 12 weeks after the end of antiviral therapy. Clinical trials conducted so far describe high tolerability and safety profile with RVS being achieved in > 95% of patients. The therapeutic failure may occur secondary to the selection of resistant mutants that cause the recurrence of viral replication (14-16).

There are currently several regimens available with an equivalent safety profile: sofosbuvir/ribavirin, sofosbuvir/ simeprevir +/- ribavirin, sofosbuvir/daclatasvir +/- ribavirin, sofosbuvir/ledipasvir +/- ribavirin, ombitasvir/paritaprevir/ritonavir/dasabuvir +/- ribavirin, sofosbuvir/velpatasvir +/- ribavirin and elbasvir/grazoprevir +/- ribavirin (17).

The regimens available in Romania are represented by ledipasvir/sofosbuvir and paritaprevir/ombitasvir/ritonavir/dasabuvir. Currently, limited availability and in-

creased costs of direct-acting antivirals require prioritization of therapy in patients with advanced liver disease.

Given the effectiveness of direct oral antiviral therapy in patients with chronic HCV infection, we aimed to describe the demographic, clinical and biological characteristics of our patients with chronic HCV infection who received treatment with paritaprevir/ ombitasvir/ritonavir/dasabuvir with or without ribavirin during December 2015-October 2016 and September 2017-January 2018.

MATERIAL AND METHODS

We performed a single-center prospective cohort study of 186 patients with chronic hepatitis C who have undergone treatment with paritaprevir/ombitasvir/ritonavir and dasabuvir with or without ribavirin during December 2015 - October 2016 (group 1) and September 2017 - January 2018 (group 2).

According to the national protocol, inclusion criteria during December 2015 - October 2016 were: genotype 1b interferon naive or experienced patients with compensated cirrhosis - F4 (Child Pugh score≤6), detectable HCV-RNA levels, absence of alcohol consumption or other intravenous/intranasal illicit substances in the last 3 months, absence of significant drug-drug interaction.

During September 2017 - January 2018, inclusion criteria were: interferon naive or experienced patients with advanced fibrosis (F3) or compensated cirrhosis - F4 (Child Pugh score≤6), detectable HCV-RNA levels, absence of alcohol consumption or other intravenous/intranasal illicit substances in the last 3 months, absence of significant drug-drug interaction; interferon naive or experienced patients with mild fibrosis - F2 with mixt cryoglobulinemia, chronic kidney disease, non-Hodgkin lymphoma, hemophilia and thalassemia major.

Patients with hepatocellular carcinoma (METAVIR score F2, F3 or F4) could be treated if they had a transplant indication or if relapse was not found (CT/MRI) more than 6 months after ablation or resection.

Patients with decompensated cirrhosis (Child Pugh score >6) and those with dysplastic nodules were excluded.

Demographic, clinical and biological data (gender, age, weight, height, body mass index, status after interferon therapy, comorbidities, concomitant medication, complete blood count, INR, total bilirubin, AST, ALT, GGT, glucose levels, creatinine, AFP) were recorded before starting treatment.

All patients underwent upper gastrointestinal endoscopy and abdominal ultrasound.

The determination of HCV genotypes and subtypes was realized by the Abbott Realtime HCV assay. The presence of mild or advanced fibrosis, cirrhosis, the viral necro inflammatory activity, and NASH was assessed by FibroMax non-invasive liver tests: ActiTest, FibroTest and NashTest.

To present our data, we used univariate descriptive statistic tools.

In the first group were included 111 patients with compensated liver cirrhosis (Child Pugh score ≤6). The diagnostic of cirrhosis was based on clinical, biological and imagistic (abdominal ultrasound) criteria. All patients had a METAVIR score according to FibroTest F3 (26.12%), F3-F4(2.7%) or F4(70.27%). In the second group were included 75 patients with advanced fibrosis or compensated cirrhosis (score Child Pugh <=6) with a METAVIR score according to FibroTest F3(41.3%), F3-F4(6.6%) or F4(52%) (tab. I).

TABLE I.

The mean age was 58.7 (SD=8.35) years for the first group and 59.6 (SD=9.6) for the second group, with the predominance of female gender in both cases. Genotype 1b was present exclusively in the first group. For patients who received antiviral treatment between September 2017 to January 2018, HCV genotyping was not performed because it was not cost-effective.

RESULTS

Median HCV RNA at baseline was 1,264,123.180 IU/mL (SD=1,835,368.49) for the first group and 1,678,718.97 IU/mL (SD=2,994,746.86) for the second group. No patients were HBV or HIV co-infected. Most patients were naive to interferon therapy. The comorbidity rate was increased in both groups: 28.82% *vs.* 49.3% had cardiovascular diseases (hypertension, arrhythmia, valvular diseases), 23.41% *vs.* 14.66% had diabetes mellitus (with or without insulin requirement), 2.7% *vs.* 10.6% had thyroid dysfunction, more commonly autoimmune thyroiditis, 1.8% *vs.* 0% had dermatological disease (vitiligo, lichen planus), 0.9% *vs.* 5.33% had psychiatric disorders (depression, anxiety, cognitive impairment), 1.8% *vs.* 1.33% had a history of cured neoplasm (colon, kidney, urinary bladder), 1.8% *vs.* 2.66 had pulmonary diseases (asthma, bronchiectasis, pulmonary fibrosis) and 0.9% *vs.* 1.33% had hematological diseases (systemic lupus erythematosus, myeloproliferative syndrome). No patient had a history of treated hepatocellular carcinoma. In both groups, the maximum number of drugs administered simultaneously with the antiviral therapy was 4. The necro inflammatory activity assessed by ActiTest highlights a high rate for severe activity for both groups - 66.6%. The prevalence of concomitant NASH assessed by NashTest (N2-severe inflammation) was 50% in group 1 and 53.3% in group 2. There were slight differences between the two groups in terms of biological constants, but without any statistical significance.

DISCUSSION

The prevalence of HCV infection in adult patients (over 15 years old) in Romania was reported at 3.2%, equivalent to 595 000 anti-HCV positive individuals with a viremic prevalence rate of 91.3% (19). Previous data suggest that the high-risk group for HCV infection in Romania is the Baby Boom generation (people born between 1946 and 1964) (20). The age distribution of our patients met the same characteristics.

The analysis of the nucleotide sequences of the HCV RNA single-stranded molecule allowed the identification of 7 major genotypes and 67 subtypes with different and complex geographic distribution (21, 22). The distribution of HCV “epidemic subtypes” is probably influenced by historical and contemporary immigration patterns.

The global prevalence of genotype 1 is forecasted at 42.2% (83.4 million individuals), with a higher rate in East Asia (more than ⅓ of cases). According to the Epidemiological National Multicenter Study (ENMS) for genotyping of HCV in Romania conducted by Grigorescu (20) between October 2015 and March 2006, genotype 1, subtype b is predominant (97.72%) in Romanian patients with chronic HCV infection. More recent epidemiologic studies show a slightly lower prevalence (92.6%) (19). Genotypes 1a (5.4%), 3 (0.8%) and 4 (1.2%) were recently introduced because of

injecting drug use (19,23). In our study sample, even not fully representative for Romanian population, HCV genotype 1b was exclusively present for those tested between December 2015- October 2016. According to the expert committee of the National House of Health Insurance, during September 2017- January 2018, genotyping was not mandatory due to lack of cost-effectiveness.

Given the relatively silent nature of HCV infection, the degree of addressability of undiagnosed patients is lower compared to those with other infections with more prominent clinical signs and symptoms. Even if the optimal timing for the initiation of antiviral therapy is unknown, lack of funds in our country has led to a gradually upscale of HCV treatment.

At present, in our country, the access to antiviral therapy with paritaprevir/ ombitasvir/ritonavir/dasabuvir is limited to patients with advanced fibrosis (METAVIR score F3) or compensated cirrhosis (METAVIR score F4 and Child Pugh score <=6) who are either treatment-naive or interferon-experienced, with or without coinfection with HBV or HIV and to patients with mild fibrosis (METAVIR score F2) interferon-naive or interferon-experienced with mixt cryoglobulinemia, chronic kidney disease, non-Hodgkin lymphoma, hemophilia and thalassemia major. Patients with hepatocellular carcinoma (METAVIR score F2, F3 or F4) may be treated if they have a transplant indication or if relapse is not found (CT/MRI) more than 6 months after ablation or resection.

According to the *"Summary of Product Characteristics as authorized by European Medical Agency",* administration of paritaprevir/ombitasvir/ritonavir/dasabuvir is not indicated in patients with decompensated liver cirrhosis (Child Pugh score B or C) (17).

Currently in Romania, the only treatment available for patients with decompensated liver cirrhosis (only Child Pugh score B) is represented by a single-tablet fixed-dose combination of sofosbuvir and ledipasvir with or without ribavirin.

In our study, although in group 2 were included patients with a lower degree of fibrosis, we didn't find statistically significant differences compared to group 1 regarding the severity of hepatic disease (baseline biological constants, comorbidities, esophageal varices, necro inflammatory activity and concomitant presence of nonalcoholic steatohepatitis). Patients with less advanced fibrosis should be included in the antiviral treatment to improve outcomes, prevent disease progression and reduce the incidence of hepatocellular carcinoma.

In august 2017, after gaining increased efficacy in phase 3 trials ENDURANCE and EXPEDITION (99% SVR12 rate for genotypes 1,2,4,6 and 91-96% SVR12 rate for genotype 3), the U.S. Food and Drug Administration (FDA) and the European Medicines Agency (EMA) have approved the use of pan genotypic combination of direct acting antiviral agents glecaprevir (NS3/4A protease inhibitor)/pibrentasvir (NS5A inhibitor) to treat patients with compensated liver disease, with or without cirrhosis (24). This fixed dose oral combination (300 mg/120 mg) has the possibility to reduce by 4 weeks the time for cure in non-cirrhotic patients with genotype 1-2, 4-6, even in those with severe kidney disease or HIV coinfection (25).

The real-world prioritization is to treat all patients with advanced disease.

Prioritization of antiviral therapy should

also be done in those who associate extra-hepatic comorbidities. In our cohort, the most prevalent comorbidities were cardiovascular diseases followed by diabetes, thyroid dysfunctions and psychiatric disorders. In these patients, there is an increased risk of significant drug-drug interactions, especially with concomitant administration of proton pump inhibitors, thyroid hormones and dihydropyridine derivates. This risk is higher in elderly patients (> 65 years), in patients with advanced liver cirrhosis and with a combination of at least two direct-acting antivirals (26). In patients undergoing treatment with paritaprevir/ombitasvir/ritonavir/dasabuvir and concomitant ambulatory medication, the risk of significant drug-drug interaction is estimated at 66.3% (26).

All patients with chronic HCV infection regardless of degree of fibrosis should receive antiviral therapy. Early initiation of DAA may improve the outcome and lower the costs.

Cost-effectiveness analysis are needed to identify different ways to redirect resources to minimize the inequality of distribution of therapy with DAA and to achieve the WHO's objective to eradicate HCV by 2030.

CONCLUSIONS

The partial results of our study show a higher prevalence of HCV infection among people born between 1946 and 1964 (baby boom generation), especially women. In this geographical area, genotype 1b was found exclusively. Most patients, naïve to interferon therapy, associate numerous comorbidities and simultaneous treatments that may decrease adherence to therapy due to the possibility of significant drug-drug interactions, requiring optimal therapeutic management and close monitoring.

ASSOCIATED FACTORS OF EJECTION FRACTION IN INSULIN-TREATED PATIENTS WITH TYPE 2 DIABETES (Abstract). **Aim of the study**: to evaluate the relation between ejection fraction (EF), diabetes characteristics and cardiovascular risk factors. **Material and methods**: We carried out a cross-sectional study in 171 patients with insulin-treated type 2 diabetes hospitalized at the Sf. Spiridon Emergency Clinical Hospital, Iasi. All patients were evaluated for asymptomatic organ damage and cardiovascular risk factors of hypertension and diabetes metabolic control. Global ejection fraction (EF) was evaluated through 2-D echocardiography. **Results and discussion:** In the studied group the ejection fraction had significant negative correlations with the duration of the disease (p=0.007) and the presence of microalbuminuria (p=0.001). There were some differences between the categories realized by grouping the patients according to the presence of hypertension and/or previous myocardial infarction. In patients without personal history of cardiovascular disease EF was correlated only with LDLc levels. In the hypertensive patients without myocardial infarction it was correlated with diabetes duration, Hb A1c and LDLc. In those patients with both conditions, EF had significant correlations with Hb A1c and microalbuminuria. **Conclusions:** These results emphasized that the determinants associated with heart failure in patients with type 2, insulin-treated diabetes, differ according to the presence of high blood pressure and myocardial infarction. **Keywords:** ARTERIAL ESSENTIAL HYPERTENSION, DIABETES MELLITUS, HEART FAILURE

Metabolic syndrome is a frequent association in hypertensive patients because insulin resistance is the main trigger of metabolic abnormalities and is related to lifestyle characteristics (1). High blood pressure is associated with primary lifestyle risk factors, and induces a large range of injuries in cardiovascular and renal system since the earliest stages (1, 2, 3, 4). Metabolic syndrome is acknowledged as the clustering of risk factors (obesity, insulin resistance, dyslipidemia and hypertension) associated with the subsequent development of cardiovascular disease and type 2 diabetes (8, 9, 10, 11, 12). The metabolic syndrome is a known risk factor for cardiovascular morbidity and mortality (1, 2); moreover, some of the antihypertensive drugs, such as beta-blockers and diuretics, have metabolic side effects that could inter-

fere and worsen the preexistent anomalies (5, 6, 7).

Diabetes mellitus (DM) and congestive heart failure (HF) are frequently associated. The presence of DM in HF patients determines an increased number of adverse events compared with patients without DM. Recent guidelines regarding glycemic control emphasized the importance of the individualization of therapy and targets depending of patient diseases and the risks associated with hypoglycemia. This balance in establishing therapeutic targets may be particularly relevant in patients with DM and HF (8).

The aim of the study was to evaluate the relation between ejection fraction (EF), diabetes characteristics and cardiovascular risk factors.

MATERIAL AND METHODS

During January 2012 and December 2013, we carried out a cross-sectional study in 171 patients hospitalized at the Sf. Spiridon Emergency Clinical Hospital, in Iasi. The inclusion criteria were the presence of insulin-treated type 2 diabetes. The exclusion criteria were type 1 diabetes, type 2 diabetes treated with non-insulinic agents, patients' refusal.

The information obtained from patients was directly registered in a well-structured questionnaire filled in as part of direct interview. The questions here comprised referred to the following aspects: demographic data, previous myocardial infarction, history of high blood pressure and duration of diabetes. The diagnosis of arterial hypertension was assessed in the presence of values higher than 140/85 mmHg, or normal ones in treated patients for high BP.

All patients underwent physical examination, laboratory investigations and diagnostic tests having as aim to search for asymptomatic organ damage and cardiovascular risk factors. A complete 12 lead ECG was registered to identify patients with previous asymptomatic myocardial infarction (MI). Global ejection fraction (EF) was evaluated through 2-D echocardiography.

We examined the relation between EF, diabetes characteristics and cardiovascular risk factors.

Continuous data was expressed as medium and standard deviation. The Shapiro-Wilk test was used to evaluate the normal distribution of the analyzed data. The chi-square test was used to determine significant differences between various categories formed out of the frequency data. Association between variables was estimated by Pearson correlation coefficient. Stepwise multiple regressions were used to identify the variables with a predictive role in ejection fraction.

The study was conducted after obtaining written informed consent in accordance with the Declaration of Helsinki. We paid full respect to the confidentiality and intimacy terms when maneuvering the data and records keeping of the participating subjects to the study.

RESULTS

We conducted a cross-sectional study on a sample of 171 patients with insulin-treated type 2 diabetes. The mean duration of the disease was 9.56 years and almost three quarters had a poor glycemic control. The criteria associated to metabolic control which were analyzed were: LDLc, HDLc, Hb A1c, microalbuminuria and blood pressure. Most of the patients had abnormal levels of these parameters, indicating a poor metabolic control (tab. I).

82.5% of the patients had high blood pressure (BP) and 24.6% had had myocardial infarction in their medical history. All normotensive patients had not had a previous myocardial infarction, while 42 (29.8%) of hypertensive ones experienced it ($p<0.001$).

The ejection fraction (EF) was also evaluated by 2-D Echocardiography, having a mean value of 54.82%. However a high proportion of the participants had cardiac failure (35.1%) (tab. I).

In the sample studied the ejection fraction had significant negative correlations with the duration of the disease ($p=0.007$) and the microalbuminuria ($p=0.001$)(fig. 1).

However, there were noticed some differences between the categories realized by grouping the patients according to the presence and/or the association of hypertension and previous myocardial infarction (tab. II).

In patients without personal history of cardiovascular disease, EF was related only with LDLc levels. In the hypertensive patients without myocardial infarction it was related with diabetes duration, Hb A1c and LDLc, while in those with both conditions, EF had significant correlations with Hb A1c and microalbuminuria (tab. II).

In the multivariate analysis, we included as potential predictors of EF the following parameters: diabetes duration, microalbuminuria, HDLc, LDLc, HbA1c.

When analyzing the entire sample, the predictors of EF were only diabetes duration and microalbuminuria ($R=0.33$, $R^2= 0.11$).

TABLE I.

	p.	.487	.11	**.002**	.096	.07	**.010**

However, we identified different predictors of EF, when analyzing on the subgroups determined by the presence of high BP and previous myocardial infarction. In diabetics without cardiovascular diseases, only one predictor was identified: LDLc (R=0.47, R^2=0.22). Hypertensive diabetics with MI had as predictors of EF, diabetes duration and microalbuminuria (R=0.30, R^2=0.09). The participants with high blood pressure, but without MI had as predictors of EF both LDLc and Hb A1c (R=0.65, R^2=0.42) (tab. III).

DISCUSSION

Diabetes is currently among the most challenging threats to public health. It is estimated that 382 million people worldwide have diabetes and the majority will likely die from cardiovascular disease (9).

In patients with type 2 diabetes, HbA1c is used to evaluate the long term glycemic control and represents an indicator of development of micro vascular and macrovascular complications. Even if the improvement of glucose control significantly reduces the risk of micro vascular complications, most of the trials failed to show if there is also a decrease of risk for atherosclerotic diseases. Despite this, the value of HbA1c is still used as a surrogate measure of anti diabetic drugs potential to lower cardiovascular risk. Some authors considered that this assumption is no longer acceptable (10).

Cardiovascular diseases are the main causes of death and disability among people with type 2 diabetes. It is estimated that 65% of diabetics would die due to heart disease or stroke. Also, they are two to four times more likely to have atherosclerotic cardiovascular diseases than adults without diabetes (11).

In our sample, 24.6% had myocardial infarction in their medical history. However a higher proportion of the participants had cardiac failure (35.1%). The incidence of HF in patients with ischemic heart disease was 35.7% in non diabetic patients, and 45.7% in diabetic patients (12). Several studies have suggested that diabetics, with or without previous cardiovascular disease,

have up to five-fold increased risk of heart failure (13).

At least 3 mechanisms are involved in inducing HF in diabetic patients: associated diaseases or favoring coronary atherosclerosis or through diabetic cardiomyopathy (14).

In the sample we studied, the ejection fraction had significant negative correlations with the duration of the disease and the levels of microalbuminuria and the predictors of EF were only diabetes duration and microalbuminuria.

Other studies, such as UK Prospective Diabetes Study (UKPDS), demonstrated a strong association between the incidence of HF and HbA1c levels in diabetic patients (15). A large trial, conducted in 48,858 diabetic patients, showed that the increase of Hb A1c with 1% was associated with a 12% increased risk of hospitalization for the same patients (16).

In our study, Hb A1c was significantly associated with EF in patients with high blood pressure even if myocardial infarction was present or not. In normotensive patients, there were no correlations between Hb A1c and EF. However, in these patients diabetes duration was a significant predictor of left ventricular systolic function.

Other studies demonstrated that the onset of HF may be better correlated with the duration of the disease. It is considered that the development of HF may be more closely related to the duration of DM than to glycemic control (14).

In patients without personal history of cardiovascular disease or high blood pressure, EF was correlated only with LDLc levels. In the hypertensive patients without myocardial infarction it was correlated with Hb A1c and microalbuminuria, while in those with both conditions, EF had significant correlations with diabetes duration, Hb A1c and LDLc.

In another study, performed in a well characterized population of patients with anterior MI and mild residual left ventricular dysfunction or preserved ejection fraction, diabetes is associated with worse functional class and a greater risk of developing congestive heart failure in the following year (13). In our study, the predictors of EF in patients with previous MI were: diabetes duration, microalbuminuria, HDLc, LDLc, HbA1c.

CONCLUSIONS

The results of our study suggested that there would be some differences between determinants associated to heart failure in type 2 insulin-treated diabetics, according to the presence of high blood pressure and myocardial infarction. Future research will clarify the extent of this association and its relevance for clinical practice.

DIFFERENTIATION OF RHEUMATOID ARTHRITIS FROM HEPATITIS C-RELATED ARTHROPATHY: CASE REPORT (Abstract): Chronic virus C hepatitis records high prevalence, almost 170 million people worldwide being infected. Systemic involvement is frequent and the implication of the osteoarticular system raises various problems in properly diagnosing and treating it. Rheumatoid arthritis is the most frequent type of inflammatory polyarthritis, with a prevalence of 0.8% in the general population. The rheumatoid factor recorded high values at virus C hepatitis patients (19-80%) even in the absence of articular manifestations, its sensitivity and specificity being reduced for the rheumatoid arthritis diagnosed simultaneous with virus C hepatitis. We report a case of chronic virus C hepatitis patient which, after 30 years of evolution, presents the onset of senile rheumatoid polyarthritis. The authors discuss the usefulness dosage of anti-cyclic citrullinated peptide antibodies for establishing the differential diagnosis between rheumatoid arthritis and hepatitis C-related arthropathy and the particularities of the specific treatment when there is a hepatitis C virus associated infection. **Keywords**: VIRUS C HEPATITIS, RHEUMATOID ARTHRITIS, HEPATITIS C–RELATED ARTHROPATHY, RHEUMATHOID FACTOR, ANTI-CYCLIC CITRULLINATED PEPTIDE ANTIBODIES.

The prevalence of virus C hepatitis (VCH) infection reaches alarming levels, worldwide being recorded almost 170 million cases (1, 2). The prevalence is maximum at the age group of 30–49 years, the infection is chronic at 80% of the patients and the progression rate towards end–stage liver disease is of 10–20%, for a period of 20 years of observation (3). Rheumatoid arthritis (RA) is the most frequent type of inflammatory arthritis, with a prevalence of 0.8% in the general population, 1.3 million adults being diagnosed with RA in the USA. Without treatment, 20 – 30% of the patients diagnosed will evolve towards a major degree of disability in the next 3 years (4, 5). The relationship between the two affections is two-way, as far as epidemiology, pathogenesis and treatment response are concerned; the traditional serological marker for RA, the rheumatoid factor (RF), was detectable at 70 – 80 % of the patients with RA, but it can have higher values also at patients with VCH, in a per-

cent of 19-80%, even in the absence of joint manifestations (6). On the other hand, serum anti–hepatitis C virus (HCV) antibodies were present in RA patient at the following levels: 5.2% and 7.6% (7, 8). We report a case of an elderly patient, which came with polyarthralgias, after more than 30 years of evolution of chronic hepatitis with HCV, at which imagistic and immunologic investigations establish the diagnosis of senile RA.

CASE PRESENTATION

An 83-year-old women, with antecedents of VCH from the age of 50 and with arterial hypertension associated with left bundle branch block from the age of 58, presents pain, tumefaction and functional incapacity at the level of metacarpophalangeal (MCP) and proximal bilateral interphalangeal (IP) joints, cervicalgia, weight loss and progressive asthenia during the past 3 months. The patient is a former nurse, has not smoked or used alcohol, and from the clinical examination resulted normal body mass index (21.5 kg/m^2), the affected joints of both hands being swollen and painful, the limitation of the cervical spine for anterior, posterior and lateral flexion, hepatomegaly with high consistency and 2nd degree splenomegaly.

Hematological and biochemical biological tests were within the normal limits, except for the increase of gamma-glutamyl transferase (ɣGT) up to the value of 89 U/L (reference range <61U/L) and moderate hepatocytolisis (ALAT 136 U/L, ASAT 134 U/L).

The abdominal ultrasound pointed out the enlargement of the right liver lobe, with micronodular hyperechoic structure and splenomegaly; the abdominal computed tomography excluded the presence of liver tumor formations. From the radiography of the hands results bilateral risarthrosis associated with clips of MCP articulations, proximal and distal IP but also periarticular osteoporosis and erosions, suggestive for the begging of RA (fig. 1). Imagistic investigations are completed by cervical spine computed tomography which excludes the presence of osteolytic lesions at this level and articular ultrasound which underlines the erosions from the II and III MCP joints accompanied by inflammatory reaction and synovitis (fig. 2, 3).

Fig. 1. Bilateral radiography of the hands showing periarticular osteoporosis and erosions

Fig. 2. Cervical spine computed tomography showing degenerative lesions

The immunological report revealed positive tests for HCV, RF increased at 70.9 UI (normal range < 16 UI), anti-cyclic citrullinated peptide (ACCP) antibodies with pathological values of 34 UI (normal range < 12 UI), cryoglobulins and antinuclear antibodies absent. The treatment was started with hydroxycloroquine in dose of 400mg/day in association with non-steroid anti-inflammatory drugs (NSAID) during hyperalgesic periods. The general state and the painful articular syndrome improved in only 3 weeks.

DISCUSSION

Chronic HCV infection is accompanied by various extrahepatic manifestations which were included by Ferri C et al. in 2007 in the so-called HCV syndrome (9), and the articular modifications are among the most frequent ones. Most studies reported polyarthralgias of variable frequency (20–83%) (1). One of the big prospective studies, which included 1614 patients with chronic hepatitis C, mentioned the prevalence of polyarthralgias of 23% (10). Arthritis are less frequent and they are characterized by symmetric polyarthritis which can be mistaken for RA or by mono or oligoarthritis, intermittent, without erosive–destructive features. Mono or oligoarticular affectation is more frequent at large joints and is associated to the presence of cryoglobulins, while symmetric polyarthritis has an evolution similar to that of RA (11-14). HCV-related arthropathy can be clinically similar to RA, many patients experiencing the diagnosis criteria stated by American College of Rheumatology (ACR) (15).

In this patient's case, the main differential diagnosis reported to senile RA and HCV associated arthropathy. The differentiation consisted in the dosage of the ACCP antibodies, which recorded higher levels and the radiographies of the hand which pointed out periarticular erosions, rare in HCV arthropathy. The comparative immunological studies at patients with chronic hepatitis C virus proved the superiority of ACCP antibodies in RA diagnosis. ACCP antibodies were scarcely positive at patients with HCV and arthralgia (5.7%), absent at the secondary Sjögren syndrome (0%) but they were present at 78% of the patients with RA (1). A previous study used for detecting ACCP antibodies a second generation ELISA kit (cut off = 20U/ml) and reported a prevalence of 6.9% (2/29) in patients with HCV and mixed crioglobulinemia and 0% (0/50) in patients without crioglobulinemia (16). In a different group of 39 patients with HCV, 31 of which with associated arthropathy, compared with 30 patients with RA criteria, ACCP antibodies were present in 77% of the patients with RA and in no patients with HCV (13). Classically, 50% of the patients with VCH present mixed crioglobulines and 24% arthralgia (1). Referring to the primary Sjögren syndrome, the

percentages are small, less than 10 % of the patients with primary Sjögren syndrome presenting ACCP antibodies (17).

VCH was associated with many other extrahepatic manifestations as vasculitis, glomerulonephritis, thyroiditis and sialoadenitis, but poliarthritis were most cited (10). Fadda et al. examined 302 patients with VCH for arthritis (8% of the patients with crioglobulinemia presented non-erosive oligoarthritis, 15% of the patients with crioglobulines experienced polyarthritis and 30% of them presented erosions at radiological investigations) (18). Among the self-antibodies produced by the organism in VCH, RF is one of the most frequent (30%-70%), sometimes present at high levels (12). Unlike RF, ACCP antibodies were not mentioned as autoimmune markers and did not record high levels at patients with VCH, included in the published studies (1, 6, 13, 16, 19-21). Lu et al. (19) also studied the diagnostic role of anti-agalactosil Ig G antibodies in differentiating RA from the other similar arthropathies, present in VCH, hepatitis B virus or primary Sjögren syndrome. They pointed out that the anti-agalactosil antibodies' sensitivity and specificity is lower than that of ACCP antibodies (81% sensitivity and 98.4% specificity), which remain the golden standard in differentiating RA from other arthropaties associated to viral hepatitis and primary Sjögren syndrome, regardless of the presence or the absence of RF. In the study conducted by Ezzat et al. (20), which included 30 patients with RA and 22 with HCV–related arthropathy, the sensitivity of ACCP antibodies was comparable to that of RF (83.3% vs 90%), but their specificity was by far higher (95.4% *vs.* 18.2%).

The apparition of ACCP antibodies in RA is the result of the migration of inflammatory cells at the level of joints where the enzyme protein – arginil deaminase (PAD) transforms the arginin amino-acid in citrulline, followed by apoptosis of articular cells (22). Up to this moment, there have been used 3 generations of tests to point out the anti-citrulline antibodies, the first generation including only antiperinuclear factor (APF) antibodies and anti-keratin antibodies (AKA). In the case of second and third generation tests, sensitivity was increased by using some combinations of synthetic cyclic citrullinated peptides (23).

In our case, the immunological investigation was completed by the imagistic assessment which helped completing the RA diagnosis criteria according to the present guides (15). The pain from the level of the cervical spine being intense, vertebral computed tomography excluded the presence of metastases, and the abdominal computed tomography was performed to underline the possible liver tumor formations. Articular symptoms could also be the expression of paraneoplastic rheumatoid syndrome, associated to hepatocarcinoma, although liver tumors are, more frequently, accompanied by various hematological disorders, hypoglycemia, myositis and neurological syndromes.

The presence of chronic VCH limits the treatment options of the associated RA. Considering the age too, we chose for our patient the hydroxcloroquine treatment associated with NSAID; the improvements were noticeable after the first weeks of treatment. Other authors also mention the possibility of using hydroxcloroquine and sulfasalazine in patients with moderate liver disorders. Cyclosporine, with antiviral effect as well, but also tumor necrosis

factor (TNF) inhibitors, rituximab and abatacept were used (3, 24).

CONCLUSIONS

This case as well as the previous reports in the literature emphasized the particularities of the RA in comparison with hepatitis C-related arthropathy and describe the utility of ACCP as laboratory diagnostic tool.

NEWS

TARGETED ANTIFUNGAL PROPHYLAXIS IN HEART TRANSPLANT RECIPIENTS

Tissot *et al* conducted a retrospective analysis to identify the risk factors for the development of invasive fungal infection (IFI) after heart transplantation (HTx) and implement a new antifungal prophylaxis policy. For this purpose, clinical characteristics of HTx recipients hospitalized during a seven years period were recorded and risk factors associated with IFI were identified using Cox regression analysis (Period 1). Based on the results of the first analysis, all recipients at high risk for IFI received targeted caspofungin prophylaxis (Period 2 of the study, lasting 3 years). During Period 1, 10% of patients developed IFI after transplantation. The use of posttransplant extracorporeal membrane oxygenation was the strongest predictor for IFI by multivariate analysis, while *Aspergillus* colonization and renal replacement therapy were significant predictors by univariate analysis. Antifungal prophylaxis was administered to 17% of patients at high risk for IFI in period 1 versus 100% in Period 2. Only 4% of the patients developed IFI during Period 2. Antifungal prophylaxis was associated with a reduction in IFI incidence and mortality. Extracorporeal membrane oxygenation is an important risk factor for IFI after transplantation and requires targeted administration of antifungal prophylaxis (Tissot F, Pascual M, Hullin R, *et al*. Impact of Targeted Antifungal Prophylaxis in Heart Transplant Recipients at High Risk for Early Invasive Fungal Infection. *Transplantation*. 2014 Feb 11).

BARRIERS OF ANTIAGGREGANT TREATMENT (Abstract): In the present study we **aimed** to evaluate side effects of antiplatelet therapy in order to establish correlations with medication type, doses and association with other therapies. **Material and methods**: in the study we prospectively evaluated a cohort of patients who received antiplatelet therapy for different pathologies. We included patients with acute coronary syndromes, valvular disease complicated with supraventricular arrhythmias (especially atrial fibrillation), carotidal critical stenosis, neurologic disease (ischemic or thrombotic), and peripheral artery disease. **Results and discussions**: The study included 125 patients (85 males and 40 females), aged between 45 and 85, and admitted in the 1st Cardiology Department, St Spiridon Hospital, between January 2012 and December 2013, who received antiplatelet therapy for different pathologies. All the patients included in the study received platelet antiaggregant therapy with Clopidogrel in association or not with Aspirin or low weight molecular heparin. Side effects reported (possibly correlated with antiplatelet therapy) were: macroscopic hematuria (7 cases), cutaneous ecchymosis (7 cases), purpuric lesions (9 cases), gingival bleeding (12 cases), upper gastrointestinal bleeding (6 cases), and hemoptysis (2 cases). **Conclusions:** Hemorrhagic events under the treatment with antiplatelet agents are rare in comparison with the large number of patients treated. Clinical manifestations are very different depending on the drug and also on the drug-associations used. Hemorrhagic accidents may sometimes be very serious, determining the specific therapeutic measures. **Keywords:** ANTIAGGREGANT TREATMENT, CLOPIDOGREL, ASPIRIN, HEMORRHAGE, SIDE EFFECTS.

Atherothrombosis accounts for 22.3 % of all causes of mortality worldwide as reported by the World Health Organization in 2001 (1). Cardiovascular disease (CVD) was defined as coronary heart disease (myocardial infarction (MI), angina pectoris, coronary insufficiency), cerebrovascular disease (stroke, transient ischemic attack), congestive heart failure, and intermittent claudication. This definition of CVD covers all the manifestations of athero-thrombosis. According to this analysis, more than 60% of men and women over 40 years of age will develop atherothrombotic disease at some point in their lives (1). For patients older than 50 years of age, the development of atherothrombotic disease reduces life expectancy by 8 to 12 years (1).

The role of platelets in athero-thrombosis is a very important factor to be considered in

preventing cardiovascular death, MI and stroke (2). After plaque rupture or vessel damage, platelets undergo three processes: adhesion, activation, and aggregation, and then a thrombus is formed. An agent that would inhibit these platelet processes would therefore definitely be beneficial and effective in preventing atherothrombotic events (3). Antiplatelet agents such as aspirin, triflusal, clopidogrel, and ticlopidine generally act on the platelet activation process while GIIb/IIIa inhibitors impede platelet aggregation by blocking activated fibrinogen receptors (3). They are widely used for primary and secondary prevention of cardiovascular and cerebrovascular diseases (4). However, use of either aspirin or clopidogrel is associated with bleeding adverse events (5).

Clopidogrel is a potent anti-platelet drug of the thienopyridine group that inhibits adenosine dinucleotide phosphate (ADP) receptors. It is considered superior to aspirin for secondary prevention after cardiovascular events, it is widely administered following cardiac catheterisation and stent implantation or bypass and its indications are expanding (5, 6). Combined aspirin and clopidogrel therapy is even more effective in preventing vascular events and associated mortality, but that regimen may significantly increase the risk for bleeding (7, 8).

The aim of this study was to assess the occurrence of antiplatelet therapy side effects in patients with CAD.

MATERIAL AND METHODS

We conducted a prospective cohort study in which we included 125 patients (85 males and 40 females), aged between 45 and 85, who received antiplatelet therapy for different pathologies, admitted in the 1st Cardiology Department, St Spiridon Hospital, between January 2012 and December 2013.

Patients with uncertain acute coronary syndrome criteria, those without clopidogrel therapy, patients with contraindication of platelet antiaggregant therapy (e.g., antecedents of hemorrhagic accidents or known hemorrhagic diatheses, previously known liver disease) as well as patients with psychiatric disorders, clinical severe thrombocytopenia, progressive malignancy or noncompliant ones were excluded.

Patients were initially evaluated following a complete check-up, including past history, clinical examination, blood tests, electrocardiogram and cardiac ultrasound. The final decision regarding study inclusion was taken after having a precise diagnosis and therapeutic scheme. They were followed up for one year, initially at one month and then at 3, 6 and 12 months.

All the patients included in the study received antiaggregant therapy with clopidogrel associated in some patients with aspirin or low weight molecular heparin.

After enrolment, patient age, sex, smoking and drinking habits, previous medications including antiplatelet agents (aspirin, clopidogrel), nonsteroidal anti-inflammatory drugs (NSAIDs), and gastroprotective agents, and past history of endoscopically proven peptic ulcer disease were recorded. During the follow-up period, data concerning hemoglobin, platelet levels, and evidence of bleeding were recorded.

RESULTS

We reviewed the records of 125 patients (68% men, average age 65.3 ± 10.1 years) with baseline characteristics (tab. I).

The most commonly associated co morbidities were hypertension (70.4 %), diabetes mellitus (35.5 %), congestive heart failure (26.6 %), and dyslipidemia (22.7 %).

The majority (77 patients, 61.6% of cases) were diagnosed with acute coronary syndromes (most cases with different forms

of unstable angina) that have satisfied the study inclusion criteria. Thirteen patients (10.4%) received antiaggregant treatment for acute and subacute MI, and 28% of the patients received antiplatelet therapy for other diseases such as: valvular disease (mitral or aortic) complicated with supraventricular arrhythmias (especially atrial fibrillation) (15 patients), carotidean critical stenosis (3 patients), neurologic disease (ischemic or thrombotic), peripheral artery disease (17 patients).

Male n, %	66 (52.8%)
Diabetes n, %	51 (40.8%)
Smoking n, %	64 (51.2%)
Blood hypertension n, %	79 (63.2%)
Cholesterol, mg/dl (mean ±SD)	229.5±45.99
Creatinine, mg/dl (mean ±SD)	0.98±0.39

All the patients included in the study received 75 mg of clopidogrel daily. In 77 patients clopidogrel was associated with aspirin 75 mg daily, and seventy-four patients (13.9%) also received low weight molecular heparin (enoxaparin). Anticoagulant treatment was associated for a medium of 7 days in patients with ACD. The majority of patients 67 (53.6%) received double antiaggregation (clopidogrel and aspirin) upon discharge (fig. 1).

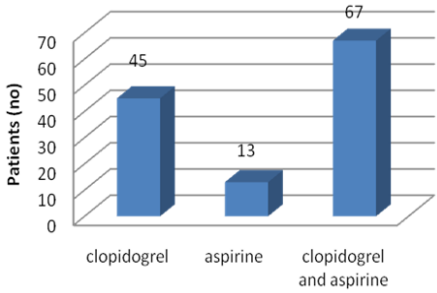

Fig. 1. Treatment received by the patients included in the study upon discharge.

During the follow-up, we recorded 7 (5.6%) cases of hematuria, between 7 and 10 days after the treatment was begun. All the patients were males and had been treated with clopidogrel and aspirin.

Seven patients (5.6%) has developed cutaneous ecchymosis after an average period of one month, four of them had a double antiaggregation, with no platelet count. Six patients (4.8%) had purpuric lesions secondary to clopidogrel treatment. All the skin lesions were reversible after clopidogrel was stopped and replaced with aspirin (tab. II).

TABLE II
Side effects in patients with antiaggregant treatment

Side effect	Clopidogrel (n=45)	Aspirin (n=13)	Clopidogrel and aspirin (n=67)
Macroscopic hematuria n, %	0	0	7 (5.6 %)
Cutaneous ecchymosis n, %	2 (1.6%)	1 (0.8%)	4 (3.2 %)
Cutaneous purpura n, %	5 (4%)	0	1 (0.8%)
Gingival bleeding n, %	4 (3.2%)	0	8 (6.4%)
Upper digestive hemorrhage n, %	0	0	7 (5.6%)
Hemoptysis n, %	2 (1.6%)	0	0

Patients with upper digestive hemorrhages had melena and also received heparin therapy. Upper digestive endoscopy was performed in half of the cases, and acute hemorrhagic gastritis was described in all the cases. Antiaggregant treatment was stopped and a proton pump inhibitor was added as treatment.

Two smoking male patients were diagnosed with haemoptysis, all of them on clopidogrel. Bronchoscopy was normal and they did not repeat the bleeding after clopidogrel was changed to aspirin.

DISCUSSION

Although some studies demonstrated that clopidogrel increases the risk of bleeding (4, 6) our findings suggested that hemorrhagic adverse events are rare in patients on antiaggregant therapy. These results may have important implications in antiplatelet therapies for patients with or at risk for cardiovascular disease.

Antiplatelet therapies are effective in reducing ischemic events, yet are likely to increase bleeding risk (7). Use of more potent antiplatelet therapies is likely to further reduce the risk of ischemic events, while simultaneously increasing the risk of bleeding (6). While these agents are effective in reducing thrombotic complications of atherosclerosis (ASC), their use increases the likelihood that patients will develop a bleeding complication (8). The reported risk of bleeding during hospitalization for ACS varies between 1 and 10% and is influenced by patient co morbidities, age, sex, rates of treatment with revascularization or invasive procedures such as angiography, intra-aortic balloon pumps or coronary artery bypass grafting (CABG) and the antiplatelet/antithrombotic treatment regimen used for treatment (9).

Prior studies have consistently identified female gender, older age, lower body mass index, low creatinine clearance, and the use of percutaneous interventions as risk factors for bleeding complications (9, 10). In order to better understand an individual's risk of bleeding, there have been several attempts to develop standardized predictive models for bleeding risk; unfortunately, the majority of these bleeding scores have had relatively poor predictive power (10).

Recently, Subherwal et al. (11) published the CRUSADE Bleeding Score using clinical criteria available at presentation such as baseline hematocrit, creatinine clearance, heart rate, sex, systolic blood pressure, diabetes, prior vascular disease, and the presence of cardiac heart failure upon presentation. Current ACC/AHA guidelines for the treatment of patients with ACS recommend dual antiplatelet therapy due to numerous studies demonstrating a reduction in ischemic complications (12). The addition of an additional antiplatelet agent does increase the incidence of bleeding, results which were also confirmed in our study.

In the CURE trial of patients with ACS randomized to clopidogrel plus aspirin versus aspirin alone, the rate of major bleeding in patients assigned to clopidogrel plus aspirin was 3.7%, while the rate in the patients assigned to aspirin alone was 2.7% (RR=1.38; p=0.001) (13). Bleeding risk was also significantly higher among patients treated with aspirin and clopidogrel who required CABG. Post hoc analysis of the CURE trial demonstrated that the bleeding risk was especially high when CABG was performed within 5 days of the last dose of clopidogrel (13).

Patients who suffer from bleeding com-

plications or require transfusions are often treated less aggressively with evidence-based medications placing them at higher risk of future ischemic events. The Prospective Registry Evaluating Myocardial Infarction: Events and Recovery (PREMIER), a registry of 2.498 patients with acute MI, found that patients with bleeding during the index MI hospitalization were less likely to be treated with antiplatelet therapy and other agents during the first 6 months after discharge (14). These findings offer insight into the current treatment of patients with bleeding complications and may help explain why patients with bleeding complications are at a significantly higher risk for ischemic events.

Bleeding events which occurred during antiplatelet therapy are relatively rare when compared to the large number of patients treated with an antiaggregant drug in mono or dual therapy. Bleeding side effect can manifest in different territories and disappear with cessation of treatment. Association between double antiaggregation and heparin therapy increased the risk of upper digestive bleeding.

CONCLUSIONS

Our study did not demonstrate an increased risk of bleeding in patients treated with clopidogrel versus aspirin, but the double antiaggregation was associated with more hemorrhagic adverse events.

NEWS

A NEW ASSAY FOR PATHOGEN GENOTYPING

A group of researchers developed a new assay for pathogen detection and amplicon genotyping, based on restriction endonuclease digestion. In the first stage, target DNA is hybridized to immobilized complementary oligonucleotide probes carrying a molecular marker (horseradish peroxidase-HRP). In the second stage, the target-probe duplex is cleaved by the restriction enzyme at the corresponding restriction site and the HRP marker released into solution is quantified colorimetrically. This assay was tested for MRSA detection, using the *mec*A gene as a target. The detection limit for the target oligonucleotide and the PCR amplicon was approximately 1 nM. The sequences of target oligonucleotides were altered in order to prove the following: mutation to the restriction site reduced the signal to zero, mutations of the sequences that flanked the restriction site reduced restriction to 50-80% of the positive control, and a minimum of 16-bp target-probe hybrid is required for a significant cleavage. The assay is able to detect the *mec*A amplicon from an unpurified PCR mixture with limits of detection similar to standard qPCR. Detection of amplicons is not affected by the presence of excess heterologous genomic DNA and because it uses two biorecognition steps, the test has a very high specificity. The study concluded that the assay is efficient, low-cost, fast (can be completed in less than 1 hour) and can also be used for analysis of different amplicons from an unpurified mixture (Smith MW, Ghindilis AL, Seoudi IA et al. A New Restriction Endonuclease-Based Method for Highly-Specific Detection of DNA Targets from Methicillin-Resistant *Staphylococcus aureus*. THYROID DYSFUNCTION AND ISCHEMIC HEART DISEASE – CLINICAL CORRELATIONS, PROGRESSIVE IMPLICATIONS AND IMPACT ON THE PROGNOSIS (Abstract): Thyroid dysfunctions are associated with systolic and diastolic heart dysfunction, hypertension, rhythm disorders, etc. Clinically significant hyperthyroidism and hypothyroidism may have an impact on the patients with ischemic heart disease. **Objectives:** Investigation of the risk of developing ischemic heart disease, of the evolution and prognosis in relation to the entire spectrum of thyroid dysfunctions. **Materials and methods:** All participants included in the study were selected from among subjects with heart disorders who were controlled with concern to the thyroid hormonal condition and who hadn't been treated previously for thyroid functional disorders. Based on these criteria we defined a study group made out of 791 subjects, divided into five lots based on the level of thyroid hormones. Once the group was formed, we conducted evaluations of the cardiovascular and thyroid status at 6 and 12 months, respectively. **Results:** In the witness lot, during monitoring 49% of the patients showed an ischemic heart disease. The main risk factors were: heart frequency of over 80 beats/min (RR=1.83), age over 60 (RR=1.47), female sex (RR=1.21) and values of triglycerides over 160 mg/dl (RR=1.23). In the group of patients with overt clinic hyperthyroidism, during monitoring 46.1% showed ischemic heart disease. The main risk factors were: heart frequency over 80 beats/min (RR=2.41), age over 60 (RR=1.67), high level of LDL-cholesterol (RR=1.53) and female sex (RR=1.31). Among the patients with overt clinical hyperthyroidism, during monitoring 53.3% showed ischemic heart disease. The main risk factors identified were: heart frequency over 80 beats/min (RR=2.01), age over 60 (RR=1.42), high levels of triglycerides (RR=1.42) and LDL-cholesterol (RR=1.32), as well as the presence of hypertension in the health records (RR=1.31). **Conclusions:** Thyroid dysfunction is a common clinical condition with a key role in the regulation of the cardiovascular system and may contribute to the evolution of the ischemic heart disease and which should be taken into consideration when patients with heart disease are treated. In this light, thyroid function needs to be evaluated for all patients with a risk for ischemic heart disease.
Keywords: HYPERTHYROIDISM, HYPOTHYROIDISM, ISCHEMIC HEART DISEASE.

Hyperthyroidism is present at 1.3% of the population (clinically overt in 0.5% and subclinically overt at 0.7%) while hypothyroidism is present at 4.6% (with clinical

significance at 0.3% and subclinical significance at 4.3%) (1).

Thyroids disorders are associated with systolic and diastolic heart dysfunction, hypertension, rhythm disorders, etc. Clinically significant hyperthyroidism and hypothyroidism may have an impact on patients with ischemic heart disease. As recently shown in numerous studies, even the subclinical hyperthyroidism may be an independent risk factor for the mortality caused by cardiovascular disorders (2). Previously, subclinical hypothyroidism was admitted as an independent risk factor for atherosclerosis and heart failure at older women (3). However, the results of these studies are sometimes controversial (4, 5, 6, 7).

The study tried to determine through a retrospective analysis (case study – control) and a subsequently prospective perspective the correlation between the thyroid status, the cardiovascular risk factors and mortality at adult patients.

MATERIAL AND METHODS

All participants included in our study were selected from among subjects with cardiovascular disorders who were subject to a control of thyroid hormone status in the 3rd Medical Clinic of "St. Spiridon" Emergency University Hospital, "Gr. T. Popa" University of Medicine and Pharmacy, Iaşi and who hadn't been previously treated for thyroid functional disorders. The study lots were constituted from 2006 to 2012.

We included among the subjects men and women, with an age varying from 22 to 86, with an average of about 60 years old, based on the serum values of free triiodothyronine (FT3), free tetraiodo-thyronine (FT4) and the thyroid-thyrotropin stimulating hormone (TSH). All patients were subject to a complete medical evaluation, laboratory exams, electrocardiogram and echocardiography. The exclusion criteria included: age < 18; hypophysary/hypothalamic disorders, pregnancy, administration of specific thyroid treatment prior to the inclusion in the study. Based on these criteria we defined a study lot made out of 791 patients who were divided into five groups based on the level of thyroids hormones: a) HYPER subclinic – 81 patients with subclinical hyperthyroidism (10.2%); b) HYPER – 165 patients with hyperthyroidism (20.9%); c) hypo subclinical – 75 patients with subclinical hypothyroidism (9.5%); d) hypo – 170 patients with hypothyroidism (21.5%); e) Witness group – 300 patients with cardiovascular modifications without thyroid dysfunction (37,9%). Once the study lot was formed we conducted evaluations off the cardiovascular status at 6 and 12 months.

The analysis was made by means o the *SPSS 13.0* package (SPSS Inc, Chicago, Illinois, USA).

RESULTS

At the witness group, during monitoring 49% of the patients showed ischemic heart disease. The main risk factors were: heart frequency of over 80 beats/min (RR=1.83), age over 60 (RR=1.47), female sex (RR=1.21) and values of triglycerides over 160 mg/dl (RR=1.23). The treatment with antiarrhytmic drugs (RR=0.88) and beta blockers (RR=0.79) administered prior to the inclusion in the study proved to be a protective factor (tab. I, fig. 1).

Among the patients with subclinical hyperthyroidism, 28.4% showed ischemic heart disease at the beginning of the study. The main risk factors identified were: the presence of hyperglycemia (RR=1.65) and

hypertension (RR=1.42) in antecedents and high values of triglycerides (RR=1.55). In the context of decompensation of thyroid disease, the treatment with beta blockers (RR=0.79), ACEIs (angiotensin converting enzyme inhibitors) (RR=0.61) and/or antiarrhytmic drugs (RR=0.48) shows a protective factor in the development of ischemic heart disease (tab. I, fig. 1).

In the group of patients with clinically overt hyperthyroidism, during monitoring 46.1% showed ischemic heart disease. The main risk factors were: heart frequency over 80 beats/min (RR=2.41), age over 60 (RR=1.67), high level of LDL-cholesterol (RR=1.53) and female sex (RR=1.31). The treatment with ACEIs, beta blockers and antiarrhytmic proved a protective factor for this group (tab. I, fig. 1).

The main risk factors leading to ischemic heart disease for the 52% of the patients with subclinical hypothyroidism included: heart frequency over 80 beats/min (RR=3.83), obesity (RR=2.55), presence of hypertension in the personal records (RR=1.97), age over 60 (RR=1.67), female sex (RR=1.61) and a high level of LDL-cholesterol (RR=1.57). In the case of the patients who, prior to the first evaluation, received beta blockers (RR=0.61) and/or antiarrhytmic drugs (RR=0.63), the medication proved to be a protective factor in the development of ischemic heart disease (tab. I, fig. 1).

Among the patients with clinically overt hypothyroidism, during monitoring 53.3% showed ischemic heart disease. The main risk factors identified included: heart frequency over 80 beats/min (RR=2.01), age over 60 (RR=1.42), high levels of triglycerides (RR=1.42) and LDL-cholesterol (RR=1.32), as well as the presence of hypertension in the personal records (RR=1.31). The treatment with ACEIs (RR=0.95), antiarrhytmic drugs (RR=0.68) and/or beta blockers (RR=0.42), administered prior to the admission in the group is a protective factor for the development of ischemic heart disease in this study group (tab. I, fig. 1).

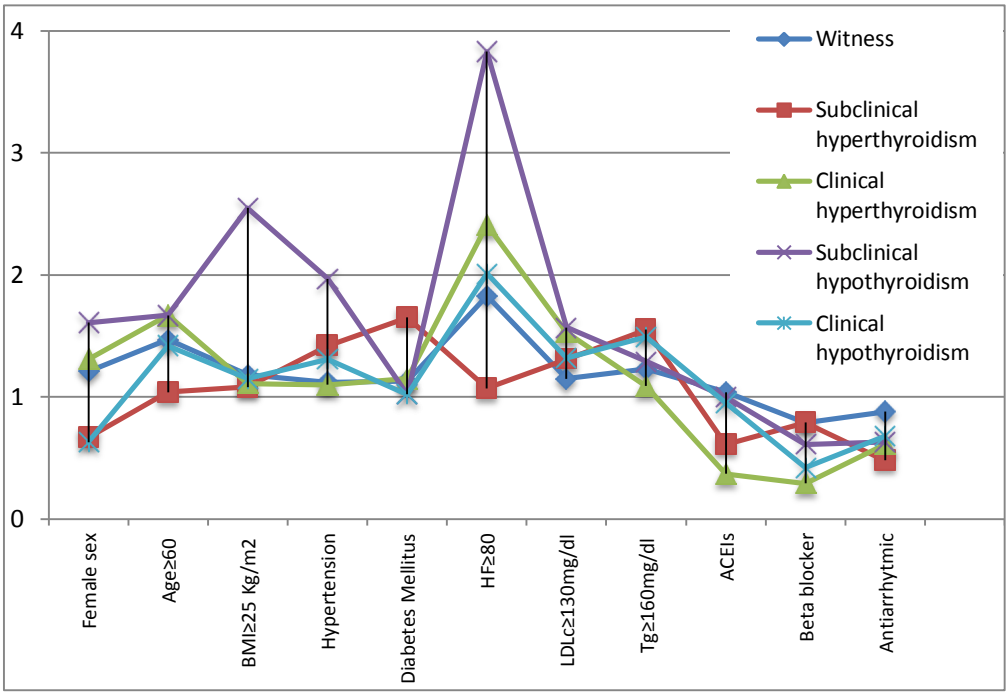

Fig. 1. Relative risk of ischemic heart disease on study lots

During the study, in the case of the witness lot, out of the 147 cases of ischemic heart disease 2 fatal events are recorded (1.4%) and 37 non-fatal events (25.2%), statistically significant proportions (p= 0.001). At the patients with antecedents of ischemic heart disease, the relative risk of developing an unfavorable event is 1.85 times higher (RR=1.85; IC95%: 1.38÷2.48) (tab. II, fig. 2).

Among the patients with subclinical hyperthyroidism who, at the beginning of the study, showed ischemic heart disease, at 15 (65.2%) were recorded non-fatal events during monitoring (p=0.002), with a relative risk 2.3 times higher (RR=2.30; IC95%: 1.45÷3.63) (tab. II, fig. 2).

At the lot with clinically overt hyperthyroidism, 28 non-fatal events are recorded (36.8%) 76 patients who, at the beginning o the study, showed in the personal pathological records ischemic heart disease (p=0.229), showing a relative risk 1.25 times higher (RR=1.25; IC95%: 0.89÷1.75) (tab. II, fig. 2).

At the lot with subclinical hypothyroidism, 7 non-fatal events are recorded (17.9%) at the 39 patients with ischemic heart disease in the records (p=0.001). At this study lot, the relative risk of an unfavorable event in the context of the presence of heart disease in the records was 2.9 times higher (RR=2.90; IC95%: 1.43÷5.87) (tab. II, fig. 2).

At the lot with clinically overt hypothyroidism, 3 fatal events (3.3%) and 46 non-fatal events (50.5%) are recorded, statistically significant proportions (p=0.001), with a relative risk 1.11 times higher (RR=1.11; IC95%: 0.85÷1.45) (tab. II, fig. 2).

DISCUSSION

Hyperthyroidism, through the cardiac hyperkinetic status it determines and thus through the increased myocardium oxygen requirement may worsen or decompensate ischemic heart disease. This mechanism is most frequently met at older patients. However, acute myocardial ischemia is rarely met in hyperthyroidism, in the absence of an already developed heart disorder (8). There are nonetheless, numerous case off hyperthyroidism which determined coronary spasm with the production of an acute myocardial infarction (8, 9).

Taking into consideration the fact that at the patients with hyperthyroidism an increase of the flow-mediated vasodilatation dependent on the endothelium was demonstrated, it is somehow paradoxical that thyrotoxicosis may induce a vasospasm, given the peripheral vasodilatation effect of thyroxine. *In vitro* studies showed an increase of contractility of smooth muscle tissues upon stimulation with various vasoconstrictor agents in case of a hyperthyroid status (10). The hyperthyroid status is associated with an adrenergic hyper stimulation which may have as an effect coronary spasm. Myocardial infarction at hyperthyroid patients may appear if the

coronary spasm is maintained long enough.

Generally, the prognosis of patients with coronary spasm associated to hyperthyroidism is favorable. Studied demonstrated the disappearance of anginous symptoms once the euthyroid status was reestablished at these patients (8).

The association between clinically overt hypothyroidism and ischemic heart disease was noticed in several studies (11). Less evident is the role of subclinical hypothyroidism, much more frequently met among patients with cardiovascular disorders. However, it was demonstrated that subclinical hypothyroidism is an independent risk factor which doubles the risk of myocardial infarction for women (12).

In a study that included patients with symptomatic ischemic heart disease, the prevalence of hypothyroidism was of 11.5%. Hypothyroidism was 4 times more frequent at women with ischemic heart disease than at men (23.4% vs. 6.9%) (11). At the level of the general population, out of which the study lot was selected, the prevalence of hypothyroidism was of 6.8% for men and of 13.8% for women. The prevalence of hypothyroidism for women was similar both under 55 years old and for above this age, which leads to a recommendation to investigate the thyroid function for all women with ischemic heart disease, regardless of their age (13).

The importance of hypothyroidism as a cardiovascular risk factor was assessed based on its association with high levels of total or LDL cholesterol. In the study conducted by Mayer O. (13), it was noticed that women with untreated hypothyroidism have higher levels of total or LDL cholesterol. Surprisingly, no similar association was found in case of men and this discrepancy couldn't be explained based on the difference in the statin therapy.

Increased serum levels of homocysteine, an important predictor for coronary disorder, were found in both men and women with hypothyroidism. Wald and coll. showed that an increase of 4-5μmol/L of homocysteine determines an increase by 32% of the risk of coronary events and by 59% of the risk of cerebrovascular events (14). The increase of homocysteine in hypothyroidism is due to a reduction of the glomerular filtration rate and a decrease of the activity of methylenetetrahydrofolate reductase, a key enzyme in the remethylation of homocysteine at methionine.

As in the case of homocysteine, an association was found between hypothyroidism, both clinical and subclinical, and the increase of reactive C protein (CRP) as well as endothelial dysfunction, evaluated through the endothelium dependent vasodilatation (15, 16). A very important aspect is that this endothelial dysfunction may be improved by the treatment of hormonal substitution with levothyroxine (16).

Taking into consideration this correlation between hypothyroidism and ischemic heart disease, the next question that arises is whether the treatment of hormonal substitution may reduce the coronary risk. Several placebo controlled trials, as well as a review showed that the levothyroxine administered to patients with hypothyroidism leads to a decrease of the total or LDL cholesterol level, failing to influence the HDL cholesterol or triglycerides (17, 18, 19).

In the recent years, several biomarkers, such as CRP and homocysteine gained an important role in the stratification of risk for patients with an alleged ischemic heart disease However, we shouldn't omit the importance of the thyroid function, which should bee evaluated for the patients at risk

for ischemic coronary disease. This could help to exclude secondary dyslipidemia. Taking into account the reverse association revealed between the serum level of FT3 and the prevalence off ischemic heart disease, as well as the correlations between the levels of FT4 and the mortality of any cause, their dosing is a rather inexpensive test which could prove useful in the stratification off coronary risk (20, 21).

CONCLUSIONS

Thyroid dysfunction is a common clinical issue with a key role in the regulation of the cardiovascular system and may contribute to the evolution of ischemic heart disease and should be take into account when patients with coronary disorders are treated. In this light, the thyroid function should be evaluated for all patients with a risk of ischemic heart disease.

DIABETES AND PERIODONTITIS

Diabetes mellitus is emerging as a global epidemic, whose complications impact significantly on quality of life, longevity and healthcare costs. The escalating human and economic burden across both the developed and developing world necessitates a multidisciplinary approach, including adjunctive measures to managing diabetes and its complications. The onset of diabetes is preceded by inflammation, which leads to pancreatic beta-cell dysfunction and apoptosis, as well as impacting on the development of insulin resistance and ultimately diabetes. It is logical that comorbidities that contribute to systemic inflammation are likely to increase the risk of developing diabetes, and impact on diabetes control and the development of diabetes complications, ultimately affecting diabetes-associated morbidity and mortality. Inflammatory periodontal diseases are the most common chronic inflammatory conditions of humans worldwide. Periodontal disease is a microbially initiated chronic inflammatory disease, in which dysregulated immune-inflammatory processes are responsible for the majority of host tissue destruction, and ultimately tooth loss. There is increasing evidence that systemic inflammation results from the entry of oral microbial agents and their virulence factors into the circulation. This is evidenced by elevated serum levels of C-reactive protein and other acute-phase reactants and raised biomarkers of oxidative stress. It is therefore biologically plausible that non-resolving chronic inflammation derived from periodontal disease impacts on diabetes control (elevated HbA1C) and complications, as well as beta-cell function, insulin resistance and development of type 2 diabetes. New researches are needed because a strong evidence base exists from epidemiological studies that periodontitis and diabetes are directly associated, and that periodontal interventions provide beneficial effects on diabetes outcomes (Iain L. C., Robert Genco. Diabetes and periodontal Diseases. *J Periodontol* 2013; 84(4 Suppl.): S106-S112).

A CROSS-SECTIONAL STUDY REGARDING THE IMPACT OF END-STAGE RENAL DISEASE ON QUALITY OF LIFE (Abstract): The number and severity of physical and psychological symptoms reported by chronic hemodialysis (HD) patients are significant and increasing; with a clear need to clarify which symptom intervention is the most needed. Measurements of quality of life (QoL) have shown, for many decades, an impairment of both physical and psychological aspects in both chronic kidney disease (CKD) pre-dialysis and in end stage renal disease (ESRD) patients. This cross-sectional study was conducted assess the quality of life of a Romanian hemodialysis population and the impact of several clinical and biochemical factors. **Material and methods:** A total of 102 patients (41 males, 61 females) with a mean age of 52.5 ± 12.0 years, who were treated with HD three times per week in our dialysis center were included in the study. All subjects completed the Short Form Health Survey Questionnaire (SF-36). Clinical and biochemical parameters were extracted from the EUCLID® electronic database. **Results:** Our measurement showed a deteriorated QoL in our population, all of the included subjects presenting with much lower scores in both physical and mental components than the reference values of SF-36. We did not found any statistic significant correlation between hemoglobin (Hgb) levels or dialysis adequacy and different domains of the SF-36. The only significant association was found between age and the physical component of the SF-36, implying that older patients perceive a more degraded quality of life. **Conclusion:** HD patients experience a great burden from physical and psychological symptoms of the disease, perceiving an important impairment in their quality of life, especially regarding the physical component. **Keywords:** QUALITY OF LIFE, END STAGE RENAL DISEASE, DIALYSIS, SF-36

End stage renal disease has become a worldwide health problem and it is associated with increased mortality and morbidity (1). The ERA-EDTA Registry (http:// www.era-edta-reg.org) collects individual and aggregated data from national and/or regional renal registries in Europe (2). According to ERA-EDTA Registry Annual Report 2010 the expected remaining life spam for patients after initiation of renal replacement therapy (RRT) is 10.7 years for patients' age between 40-44 years and 5.6 years for patients' age between 60-64 years (3).

It is well known the fact that patients with ESRD present with major life disturbances caused by a multitude of factors: severe cardiovascular and metabolic complications, treatment, dietary and fluid restriction, the dependency of the dialysis machine and the stringency of the dialysis schedule (4). All of these imply an important psychological, social, familial and professional impact, potential losses and lifestyle changes for the ESRD patients.

Health related quality of life (HRQoL) is a concept developed for the first time in 1946 when the constitution of the World Health Organization (WHO) defined heath as 'a state of complete physical, mental and social well being and not merely the absence of disease or infirmity' (5). Nowadays, this definition has been extended also to the effects of a person health (including the effects of both disease and its treatment) on physical, cognitive and social functioning in day to day life (6).

ESRD patient's high burden of the disease is also experienced by most individuals suffering from different chronic illnesses. The association between deteriorated quality of life and non-renal chronic diseases was reported in various medical specialties: diabetes (7), cardiovascular diseases (8), pulmonary diseases (9), neurologic diseases (10), rheumatologic diseases (11), all of these studies showing a disrepair in different domains of the quality of life when a long term illness is instituted.

The same results were found in the renal population, both chronic kidney disease pre-dialysis stages and ESRD population on different RRT (hemodialysis or peritoneal dialysis (PD)). Impaired quality of life and the relationship between illness perception (IP) and perceived quality of life were reported previously by our group (12) in a Romanian HD population without significant co morbidities. This study found that illness perception could be interpreted as a powerful predictor of QoL in ESRD patients.

Since improvement of the quality of life has become a major treatment goal in ESRD patients, the aim of this study was to evaluate the QoL of a well-established cohort of Romanian patients receiving HD treatment and to analyze the impact of several clinical and biochemical parameters on this psychosocial measurement.

STUDY DESIGN

We performed a cross-sectional questionnaire analysis in HD patients in order to determine the prevalence of severity of the psychological and physical symptoms and to evaluate the quality of life in these patients.

PATIENTS AND METHODS

We included a total of 102 stable patients (41 males and 61 females) with a mean age of 52.5 ± 12.02 years who were receiving HD treatment three times weekly in *Fresenius Nephrocare* Iasi dialysis unit. All subjects were informed about the purpose of the study and gave written consent prior to participation. All subjects completed the Short Form Health Survey Questionnaire in order to assess the QoL.

The data were analyzed using *SPSS version 22.0* for Mac. Frequencies and descriptive statistics of the demographic and symptoms data of the study population were calculated. We used independent t-test for independent variables to compare the means and to observe the influence of independent variables on the dependent variables. ANOVA was used to assess the

relationship between QoL and continuous variables (age, hemoglobin (Hgb), Kt/v).

INSTRUMENTS

The SF-36 adapted for Romanian population was used to assess eight dimensions of the QoL: physical functioning, social functioning, role-functioning emotional, role-functioning physical, vitality, bodily pain, mental health and general health perception. Two summary score were obtained: one for the physical component (assessing physical functioning, role-functioning physical, vitality, bodily pain and general health perception) and one for the mental component (assessing social functioning, role-functioning emotional, mental health, vitality, and general health perception). Score ranged from 0 to 100, a higher score indicating a better perceived quality of life.

RESULTS

A summary of demographics and clinical data is shown in table I (n=102). The mean age of the sample was 52.51 years (±12.02). All included subjects were Caucasian and the majority was constituted by female (59.8%). The mean Hgb level was 10.9 g/dl (±1.06). On average, patients received adequate dialysis as indicated by a mean Kt/V of 1.47 (±0.27). The mean scores for the SF-36 Physical Component Score (PCS) and Mental Component Score (MCS) were 51.87 (±19.21), respectively 61.38 (±16.71) suggesting a decreased perceived quality of life among the analyzed population.

TABLE I

Baseline characteristics of the included patients

Variable	Statistics
Mean age ± SD years	52.51±12.02
Male, n(%)	41(40.2)
Ethnicity (Caucasian), n(%)	102(100)
Mean hemoglobin ± SD, g/dl	10.99(1.06)
Mean Kt/V ± SD	1.47(0.27)
PCS	51.87(19.21)
MCS	61.38(16.71)

SD=standard deviation; PCS=physical component summary;
MCS=mental component summary;

Table II summarize the mean score for each of the eight domains of the SF-36 that were evaluated. The lowest score was registered by the role-functioning physical domain with a value of 36.61(±36.21) suggesting that ESRD patients seem to perceive the highest burden from the physical restriction of the disease.

Also, we analyzed the influence of Hgb level on PCS and MCS. There were no significant differences between the three groups in the general scores of QoL (p=0.237) (tab. III, IV). The analysis was conducted with One Way ANOVA.

TABLE II
Mean scores for each domain assessed by the SF-36

SF-36 domain	Score, mean (SD)
Physical functioning	54.63(28.52)
Role-Physical	36.61(36.21)
Bodily Pain	68.77(23.64)
General Health	45.20(21.90)
Vitality	54.41(19.87)
Social Functioning	61.95(28.07)
Role-Emotional	78.84(36.44)
Mental Health	66.39(20.79)
Physical Component Summary (PCS) score	51.78(19.21)
Mental Component Summary (MCS) score	61.38(16.71)

TABLE III
Mean scores of Hgb levels in relation to PCS score

Hgb level	N	Mean (SD)
<10	16	47.57(17.93)
10-11.5	58	50.54(18.47)
>11.5	28	56.77(21.03)

p=0.237

TABLE IV
Mean scores of Hgb levels in relation to MCS score

Hgb level	N	Mean (SD)
<10	16	58.19(15.26)
10-11.5	58	60.90(17.25)
>11.5	28	64.20(16.51)

p=0.494

We did not found any significant correlation between Kt/V and the general scores of the SF-36, suggesting that an adequate dialysis does not have an impact on quality of life in our population (table V, VI).

TABLE V
Mean scores of Kt/V in relation to PCS score

Kt/V	N	Mean (SD)
<1.4	44	51.74(20.54)
>1.4	58	51.81(18.32)

p=0.277

TABLE VI
Mean scores of Kt/V in relation to MCS score

Kt/V	N	Mean (SD)
<1.4	44	61.68(17.96)
>1.4	58	61.15(15.86)

p=0.561

The analysis showed that the only statistical significant influence (p=0.051) was found regarding age and the physical component of the SF-36 (tab. VII), indicating that the elderly patients report a more deteriorated quality of life, especially in the physical component. There were no significant differences between the two age groups in patients mental component score (p=0.098) (tab. VIII).

TABLE VII
Mean scores of age in relation to PCS score

Age (years)	N	Mean (SD)
<45	27	53.96(16.99)
>45	75	51.00(20.00)

p=0.051

TABLE VIII
Mean scores of age in relation to MCS score

Age (years)	N	Mean (SD)
<45	27	62.82(13.17)
>45	75	60.86(17.87)

p=0.098

The analysis regarding the influence of Kt/V and age on QoL was conducted with Independent samples t-test.

DISCUSSION

Dialysis care has increased in importance throughout the world because of the growing prevalence of patients receiv-

ing RRT and its related mortality and morbidity and high social and financial costs. The multidimensional aspects of quality of life of these patients have been reported previously in literature and include not only a general perception, but also specific aspects of physical, psychological and social functioning.

Our primary objective was to assess HRQoL in our study group sample. According to our results, and consistent with other literature data (13), there appears to be an important impairment to QoL in our population. All of the eight domains that were evaluated were below the reference values established by the SF-36 questionnaire, the most heavily affected components being role-physical functioning, vitality and physical functioning. The worst SF-36 score was for the general health section (PCS=51.78) implying that patients on RRT have a negative self-assessment of current health.

Our secondary objective was to identify several clinical and biochemical parameters that could be significant predictors of HRQoL.

Regarding the dialysis parameters, our results are both conflicting and consistent with other studies. We found that our population presented a mean Kt/V of 1.47, but no statistical significant association between the general scores of SF-36 and Kt/V, suggesting that dialysis adequacy had no impact on quality of life on our population. These data support the results found by the HEMO study (14), a randomized controlled trial (RCT) that was designed to test the hypothesis that a higher dose of dialysis could modify different outcomes and did not found any significant differences between the two dosage groups regarding mortality, hospitalization or other secondary endpoints including quality of life. In contrast a cross-sectional survey performed on 128 HD patients with an average Kt/V level greater than 1.3 showed that dialysis adequacy was significantly associated with a better HRQoL (15).

The KDIGO Clinical Practice Guideline for Anemia in Chronic Kidney Disease 2012 (16) recommends for HD patients that erythropoiesis-stimulating agents (ESA) therapy should be started at a Hgb level between 9-10 g/dl (level of evidence 2B). Since this guideline is also suggesting that individualization of therapy can be necessary as some patients may present improvements in quality of life at Hgb concentration above 11.5 g/dl, if they are prepared to accept that risk (level of evidence not graded), in our study we divided our population according to their Hgb levels into three groups: <10 g/dl, between 10 and 11.5 g/dl and >11.5 g/dl. We did not found any statistic significant association between Hgb level and HRQoL, in contrast to a RCT that showed a more important improvement in the SF-36 scores in a higher Hgb group compared to a lower Hgb group (17).

Consisting with previously reported data (18,19) demonstrating that SF-36 scores are negatively associated with age and that QoL seems to be deteriorated in elderly HD patients, our study found a statistical borderline negative association between age and QoL general physic component score (p=0.051).

CONCLUSION

It seems that hemodialysis patients experience a great burden from physical and psychological symptoms of the disease, perceiving an important impairment in their quality of life, especially regarding the physical component. Our findings are not

alone in suggesting the imperative need to design effective interventions, such as the implementation of different types of programs for physical activity that are stimulated by social support networks (for example creating patient groups or involving family members for carrying out various activities).

NEWS

SEVERE ADVERSE EVENTS CAUSED BY MSSA ANTIMICROBIAL TREATMENT IN BONE AND JOINT INFECTION

Because the safety of prolonged antimicrobial therapy, recommended in methicillin-susceptible Staphylococcus aureus (MSSA) bone and joint infection (BJI), and risk factors for severe adverse events (SAE) were unknown in clinical practice, Valour and co. conducted a retrospective cohort study (2001-2011) analysing antimicrobial-related SAE (defined according to Common Terminology Criteria for Adverse Events) in 200 patients with MSSA BJI. The patients were admitted in a reference regional centre with acute (66%) or chronic arthritis (7.5%), osteomyelitis (9.5%), spondylodiscitis (16%), or orthopaedic device-related infections (67%) and received anti-staphylococcal therapy for 26.6 weeks. Thirty patients (15%) had 38 SAE, including 10 hematologic reactions, 9 cutaneo-mucosal reactions, 6 acute renal injuries, 4 hypokalaemia, and 4 cholestatic hepatitis. The most frequently implicated antimicrobials were anti-staphylococcal penicillins (ASP) (13 SAE/145 patients), fluoroquinolones (12/187), glycopeptides (9/101), and rifampin (7/107). To determine risk factors for the occurrence of antimicrobial-related SAE were used Kaplan-Meier curves and stepwise binary logistic. They found that only age (p=0.006) appeared to be independent risk factors for SAE. Daily dose (p=0.014) and obesity (p=0.018) were associated with occurrence of SAE only in patients receiving ASP or rifampin. The high rate of SAE and their determinants highlighted the importance of the management and follow-up of BJI, with a particular attention to be paid in elderly, especially for ASP dosages, and in rifampin dose adjustment in obese patients. (Valour F, Karsenty J, Bouaziz A et al. Antimicrobial-related Severe Adverse Events during Treatment of Methicillin-Susceptible Staphylococcus aureus Bone and Joint Infection. *Antimicrob Agents Chemother*. 2013 Nov 18. [Epub ahead of print]).

ANNEXINS, CALCIUM-DEPENDENT PHOSPHOLIPID BINDING PROTEINS IN IRREDUCIBLE HEART FAILURE (Abstract): **Aim:** To analyze the expression and distribution of annexins V and VI in intact human hearts and in dilated cardiomyopathy (DCM) in patients with irreducible heart failure. **Material and methods:** The study included nine patients with DCM and irreducible heart failure. By immunoblotting and indirect immunofluorescence, the amount and location of annexins was determined using samples of left ventricular (LV) myocardium collected during orthotopic heart allotransplantation. Samples of LV myocardium from 9 individuals who died of craniocerebral trauma served as controls. **Results:** Quantitative analysis showed an increased level of both annexins in the myocardium of DCM patients compared with normal myocardium: 122 ± 5% ($p < 0.05$) and 119 ± 5% ($p < 0.05$) for annexins V and VI, respectively. In the intact heart annexin V was located at the sarcolemma and intercalated discs, while in the myocardium with heart failure mainly in the interstitium. In normal hearts, annexin VI was located at the sarcolema, including *T*-tubules, *Z*-lines and intercalated discs. In heart failure, annexin VI was also located in the interstitium. **Conclusions:** Redistribution of annexins V and VI in the cardiomyocytes in the interstitial space may have important functional consequences and indicates the role of myocardial protein expression disturbances in the etiology and/or pathogenesis of heart failure in patients with DCM. **Keywords:** ANNEXINS, CARDIOMYOCYTES, HEART FAILURE, DILATED CARDIOMYOPATHY.

Annexins constitute a family of proteins characterized by their ability to bind phospholipids in a calcium-dependent manner. Although the biological role of annexins remains unknown, they are involved in various intra and extracellular processes, including mitogenic signal transduction, differentiation, transmembrane events, calcium flux, and extracellular matrix binding (2, 4 , 5, 6, 9, 10, 11). The annexin family proteins are present in all animal tissues, and annexins V and VI are the major cardiac proteins (2, 4, 6). Annexin V forms a voltage-dependent calcium channels and modulates the activity of protein kinase C and phospholipase A2 (3, 7, 12,

13). Annexin VI was located at the sarcolemma and intercalated discs of myocytes in rats, bovines and guinea pigs (1, 10, 11). Annexin VI overexpression in transgenic mice heart was demonstrated in dilated cardiomyopathy with disturbed cardiac contractility or intracellular calcium turnover imbalance. However, the potential role of annexins in heart failure can not be considered without establishing their precise distribution in human heart with or without heart failure. The purpose of this study was to study the expression and distribution of annexins V and VI in the healthy human heart and in patients with dilated cardiomopathy and irreducible heart failure.

MATERIAL AND METHODS

The study included nine DCM patients (8 men, 1 woman, mean age 29 ± 8 years) with irreducible heart failure. To determine the amount and location of annexins samples of left ventricular myocardium from excised hearts collected during orthotopic heart allotransplantation. Samples of left ventricular myocardium from 9 adults (7 men, 2 women, mean age 33 ± 8 years) who died of craniocerebral trauma served as controls.

Quantitative determination of annexins

Annexins V and VI content in myocardial samples was determined by immunoblotting using membrane fractions of normal and DCM human myocardium isolated according to the method of Rannou et al. (8) or Seint-Beuve et al. (1997) The LV tissue sample (150 mg) was homogenized with a homogenizer, Polytron PT knife 10 (3 times for 5 seconds each and 30 seconds pauses) in 10 ml buffer containing 0.3 M sucrose, 20mM HEPES, 1 mM NaN3, pH7.4, and protease inhibitors (1.1 mcrM leupeptin; 0.7 mcrM aprotinin, 0.7 mcrM pepstatin A; 120mcrM phenyl methane sulfonyl fluoride, 1 mM diisopropyl fluorophosphate, 1 mM iodoacetamide). All procedures were performed on ice. The homogenate was centrifuged for 45 minutes, 41.000g. The precipitate was resuspended and then homogenized in a buffer (pH6.8) consisting of 0.3 M sucrose, 30mm imidazole, 1 mM sodium azide, 100 mM NaCl and protease inhibitors. The 10% polyacrylamide gel electrophoresis in the presence of sodium dodecyl sulphate was carried out by the Laemmli method (1970). Electrical transfer of proteins to nitrocellulose membrane (Hybond ECL, Amersham) was performed according to the method of Towbin et al. (1979) in Tris-Glycine buffer system (PH8), over one hour at a voltage of 100V. Immunodetection of proteins on the membrane was performed using specific antibodies as previously described (Sambrook, Fritsch, Maniatis, 1989, Molecular Cloning A Laboratory Manual). Nonspecific interactions were blocked by incubating the membrane in phosphate saline buffer with 5% skim milk and 0.1% Tween 20, pH7.4. Then, the membrane was incubated for one hour in the primary antibody solution (1:5000) at room temperature, in blocking buffer and washed three times, 15 minutes each, in phosphate saline buffer, followed by incubation in secondary antibody (peroxidase conjugated anti-rabbit IgG) (Sigma). Membrane signal was detected by chemiluminescence reaction using the ECL kit (Western blotting detection reagents, Amersham, England) and radiological Fudgy Film (Germany). The bands were quantitatively analyzed by scanning densitometry. The results are presented as mean ± standard error. Accuracy of differences between the control and experimental groups was calculated using the Student

two-sample T-test, and the differences were considered accurate when close to $p < 0.05$. Antibodies to annexins V and VI (primary antibody) were obtained by immunizing rabbits with recombinant human annexins; these were highly specific.

Immunofluorescence histochemistry

Cellular localization of the studied proteins was done by the indirect immunofluorescence method. To do this, cryosections were fixed in a 1:1 mixture of acetone-methanol for 20 minutes at 20 ° C, processed in a 5% bovine serum albumin solution in phosphate buffer, for 30 minutes, with primary antibodies: mouse sarcomeric α-actinin or actin monoclonal antibody (Sigma) (1:10000 in phosphate buffer, 37° C) and rabbit annexin V or VI antibodies in suitable dilution (1:50 in phosphate buffer, 37° C). After triple washing in phosphate buffer, the sections were incubated successively for 30 minutes at room temperature with secondary antibodies: mouse immunoglobulin antibody conjugated with *Alexa green* fluorochrome (594nm), and rabbit immunoglobulin antibody (1:2000) conjugated to *Alexa red* (488nm). Sections were analyzed with an Opton fluorescence microscope (Germany).

RESULTS

Immunoblotting

By this method bands of annexin V (36cDa) and annexin VI (68cDa) were detected in the LV membrane fractions both in normal myocardial samples and in those from patients with heart failure (fig. 1).

The signals of both annexins were stronger in the myocardium with heart failure. Quantitative analysis indicated a definite increase in the level of both annexins in the myocardium of patients with DCM, compared with normal myocardium: 122 ± 5% ($p < 0.05$) and 119 ± 5% ($p < 0.05$) for annexins V and VI, respectively.

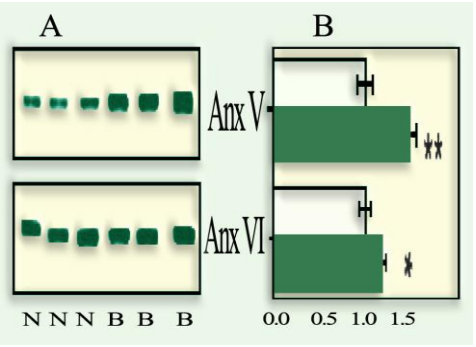

Fig. 1. Imunoblott-analysis of annexins V and VI in normal and DCM myocardium. A relative number of annexins V and VI in the healthy hearts (bright columns) and in the myocardium of patients with DCM, (dark columns). The levels are marked * $p = 0.05$, ** $p < 0.05$.

Immunofluorescence investigation

By indirect immunofluorescence in cardiac tissue cryosections differences in cellular localization of the studied annexins between normal and DCM hearts were detected (fig. 2).

Comparison of actin and annexin V location indicated that in the normal heart annexin V is located at the sarcolemma and intercalated discs. On longitudinal sections one can see that annexin V is located near the Z-lines, also labeled by actin (fig. 2, A-C).

On the cross-sections of normal myocardium notable were the invaginations – T- tubules containing annexin V, implying that annexin V was located on/near-T tubules. On the cross sections of DCM myocardium annexin V was absent in T-tubules and poorly stained the sarcolemma. On the longitudinal section of the DCM myocardium annexin V stained less brightly in sar-

colemma and intercalated discs. Comparison of annexin V and alpha-actin distribution showed that in the myocardium with heart failure, annexin V is mainly located in the interstitium, between concentrations of myocytes, where alpha-actin was not labeled (fig. 2, DF). Like annexin V, in normal hearts annexin VI is located in the sarcolemma, including T-tubules, Z-lones and intercalated discs. The cross-ribbed structure of cardiomyocytes stained with annexin VI was observed in the myocardium of patients with heart failure. In longitudinal sections of myocardium with heart failure it was seen that annexin VI is also present in the interstitium between myofilament bundles, highlighted by alpha-actinin staining (fig. 2, F).

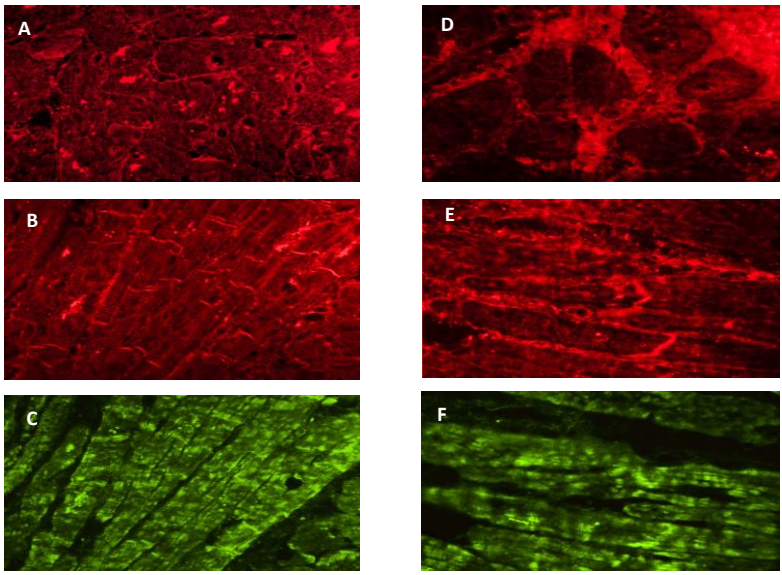

Fig. 2. Location of annexins V and VI in normal hearts (A-C) and myocardium of patients with DCM and heart failure (D-F). Immunofluorescence of cross sections (A) and longitudinal sections (B) of normal and heart failure myocardium (D and E), labeled with antibodies to annexins V and VI (50mm band).

RESULTS AND DISCUSSION

Our data showing increased annexin V and VI levels in the left ventricular myocardium of patients with DCM compared to healthy individuals are consistent with studies in patients with terminal heart failure, in which increased levels of mRNK and annexins V and VI were found. This demonstrates that the accumulation of mRNK and protein results from transcriptional regulation. Data in the literature show increased annexin V levels in the myocardium of patients with DCM and ICC and severe heart failure. However, we found an increase in annexin VI undetected by the authors of these studies. A similar increase in the amount of annexins V and VI was found in hypertensive rats with early-stage heart failure, while in compensatory hypertrophy the amount of annexin

V remained unchanged, which allows us to assume that the expression of ansexins varies with the severity of cardiac disease. To elucidate the consequences of annexin regulation in heart failure we studied their distribution. Our results showed that in the healthy myocardium the subcellular location of anexins V and VI is at the sarcolemma, intercalated discs and T-tubules, linked to the terminal cisternae of sarcoplasmic reticulum, in the complex where excitation-conjugation coupling takes place (12, 13). Comparison of annexin V and actin distribution showed that in the myocardium of patients with heart failure annexin V is mainly located in the interstitium between myocyte concentrations in areas corresponding to fibrous tissue. This redistribution is the clearest feature/ indication of a failing heart. In experiments on mice the redistribution of annexin V is a rare finding in end-stage heart failure and is absent in compensatory myocardial hypertrophy (13), although the location of annexin V in normal cardiac tissue is the same in both biological species. The ability of annexin V to bind to extracellular matrix proteins (12, 14) probably contributes to the development of "reactive" interstitial fibrosis and structural reorganization of cardiac ventricles in heart failure. Decrease of membrane-bound annexin V in myocytes can lead to a local change in Ca2 + concentration leading to the activation of protein-kinase C (10), phospholipase A2 (11), and signaling pathways (12), which contributes to the contractile cardiac dysfunction in CMD patients with terminal heart failure. Annexin VI is a negative inotropic factor, its activity being related to the regulation of the cytoplamic intracellular calcium flux by slowing the removal of calcium during diastole. All the above mentioned clearly indicate the role of annexins V and VI in the emergence and progression of heart failure in patients with DCM.

CONCLUSIONS

In the CMD patients with irreducible heart failure the amount of annexin V and VI in the myocardium increases; moreover, annexin V is mainly located in the areas of fibrosis. The ability of annexin to bind to extracellular matrix proteins indicates its participation in ventricular remodeling in heart failure. Redistribution of annexins V and VI in the cardiomyocytes in the interstitial space may have important functional consequences and indicates the role of myocardial protein expression disturbances in the etiology and/or pathogenesis of heart failure progression in patients with DCM.

VERAPAMIL IN SHORTENING TB TREATMENT

Tuberculosis (TB) is one of three leading causes of death due to a single pathogen. The increased prevalence of multidrug-resistant TB is due to low adherence to drug treatment caused by side effects and long time therapy. One of the mechanisms of resistance to anti-TB drugs is intervention of mycobacterial efflux pumps that reduce the effectiveness of antibiotics. The inhibition of these pumps enhances drug efficacy. Verapamil that is a calcium channel blocker used in treatment for high blood pressure also is an efflux pump inhibitor. A recent study in mice conducted by Gupta and colleges showed that Verapamil used in combination with isoniazid and rifampicin accelerates bacterial clearance by 10-fold after two months of treatment and the bacteriological cure is achieved after four months of therapy instead of the six. These findings supported future studies on efflux pump inhibitors to shorten TB treatment duration and increase compliance of treatment. THE ROLE AND INTERACTIONS OF GHRELIN CONCERNING THE NUTRITIONAL AND INFLAMMATORY STATUS **(**Abstract): Ghrelin is an important neuroendocrine peptide having as main purpose the stimulation of growth hormone (GH) secretion. It is also an important regulator of the long-term energy balance and short-term nutritional intake. Ghrelin has several other biological actions, among which the capacity to regulate gastrointestinal motility, to modulate the reproductive and stress axes **as well as** the glucose metabolism, and other well-defined actions within the cardiovascular and renal physiology. Due to its numerous effects, ghrelin is considered on one hand a potential target in the treatment of obesity and on the other, a therapeutic option in other dysfunctions and illnesses. **Keywords**: GHRELIN, GHRELIN-O-ACYL-TRANSFERASE, INFLAMMATION, OBESITY, CACHEXIA.

The term "ghrelin" originates from the Proto-Indo-European language, where "ghre" means "to grow" and "relin" means "release". The gene for ghrelin is located on chromosome 3p26-p25, encoding a protein of 117 amino acids named pre-proghrelin (1). This protein is processed post-transcriptionally into a 28 amino acid and 3,3 kDa peptide, synthesized especially in X/A-like cells of the gastric mucosa and to a smaller degree in the entire organism. X/A-like cells are a type of endocrine cells situated in the middle and lower regions of the gastric oxyntic glands that represent about 20-30% of all gastric endocrine cells, therefore occupying the second place within the gastric endocrine cell populations (2).

There are two isoforms of mARN for pro-ghrelin, one for ghrelin and the other one for des-Gln^{14}-ghrelin precursors, and they are produced in the rat stomach by an alternative splicing mechanism (3). Des-Gln^{14}-ghrelin is found in limited amounts only in the stomach, which proves that the physiologically important peptide is actually ghrelin, being the one released in the general circulation (3).

In the serum, ghrelin is found in 2 forms: non-acylated ghrelin, predominant in the plasma and acylated ghrelin. The latter is produced post-translationally by esterification of the hydroxyl group of the third amino acid residue, serine, by n-octanoic fatty acid, increasing the hydrophobicity of the molecule. This change allows acylated ghrelin to bind to the growth hormone secretagogue receptor 1a

(GHS-R1a), manifesting thereby its biological activities including growth hormone secretion, appetite regulation, modulation of insulin secretion, and stimulation of adiposity (4).

The enzyme responsible for ghrelin acylation was found in humans in 2007 as the forth member of the membrane-bound O-acyl-transferase family and was named GOAT (ghrelin-O-acyl-transferase). It is a well-conserved protein across vertebrates with a similar sequence in humans, rat and mouse (74.5% identity and 98.4% similarity). The endocrine cells expressing GOAT are found in the murine stomach, especially in the middle portion of the oxyntic glands, a localization which corresponds to the X/A-like cells that secrete ghrelin (5).

In rats and mice, GOAT has also been found in the plasma, which could suggest an extracellular ghrelin acylation. GOAT concentration after 24 hours of fasting increases significantly and can lead to an increase in acylated ghrelin concentration, enhancing the orexigenic effect of the latter. This represents a supplementary mechanism, apart from the gastric ghrelin mRNA expression increase as a response to fasting, to the decrease in ghrelin concentration in the X/A-like cells and increase of plasma levels of ghrelin in mice, as well as in rats.

Ghrelin has a wide distribution in human tissues and the distribution of GOAT follows the same pattern (6), allowing therefore active ghrelin to manifest its effects. GOAT expression is lower than that of ghrelin, without a statistical correlation between the expression of ghrelin and GOAT mRNA. The mRNA for GOAT is mostly found in the pancreas, stomach and pituitary, where the endocrine, paracrine and autocrine effects of ghrelin have been described.

The importance of GOAT and ghrelin in human physiology was demonstrated by knock-out studies on mice under severe caloric restriction (60%). The absence of ghrelin with the consecutive decrease in growth hormone leads after 7 days to sever hypoglycemia in the hours that precede feeding (7).

Ghrelin receptor has been known long before the discovery of ghrelin in 1999. The cells of the anterior pituitary present a receptor that, once activated, stimulates growth hormone secretion. This receptor has been named the growth hormone secretagogue receptor (GHS-R). It is encoded by a gene localized on chromosome 3q26.2. There are two types of GHR: GHS-R1a with a more limited distribution and GHS-R1b, with inhibitory effects on the GHS-R1a signaling, much more widely distributed in tissues (8). GHS-R1a is a G-protein coupled receptor that contains 366 amino acids and 7 transmembrane domains.

Ghrelin's actions on the energy balance are mediated partially through its effects on the centers of appetite, such as the central melanocortin system. Ghrelin activates GHS-R localized in the pituitary and the neurons that contain Growth Hormone Releasing Hormone (GHRH) in the hypothalamic arcuate nucleus, thereby stimulating the secretion of GH. Activating the GHS-R situated on the arcuate and ventromedial neurons leads to an increase in the expression and release of orexigenic peptides neuropeptide Y (NPY) and agouti related-peptide and to the decrease of the expression of pro-opiomelanocortin, with its anorexigenic effects. These effects lead to a decrease in the signaling taking place on the melanocortin-4 receptor and an increase in signaling in the Y1 receptor, re-

sulting in the accentuation of food-seeking behavior and in the decrease of basal metabolic rate (9).

Ghrelin and other hormones

The stimulatory effect of ghrelin on GH secretion is specific, potent, dose-dependent and synergistic with that of GHRH. In humans, ghrelin induces a significant and durable increase in the level of circulating GH, an effect more potent than that produced by GHRH itself.

Central regulation of feeding is based on ghrelin and leptin, which signal the nutritional status and the level of energy deposits to the hypothalamic feeding centers. Ghrelin is orexigenic when administered both centrally as well as peripherally and is one of the humoral signals regulating the appetite. Leptin on the other hand is an anorexigenic hormone secreted by the adipose tissue, involved in thermogenesis and the control of several neuroendocrine functions of the hypothalamic-pituitary-adrenal axis.

Knock-out mice for ghrelin as well as knock-out mice for GHS-R are not anorexic dwarfs as expected; their size, growth rate, food intake, body composition, reproduction, behavior and tissue pathology are not different from those of the wild types (10). Fasting leads to an identical decrease in serum leptin and insulinemia in mutant mice as well as in the wild ones, demonstrating that ghrelin does not have a direct regulatory effect on leptin or insulin. Knock-out mice for ghrelin present normal responses to starvation and diet-induced obesity (10). As in wild mice, exogenous ghrelin administration stimulates appetite (10). Insulin-like Growth Factor 1 (IGF1) level and weight of the mature GHS-R null mice are slightly reduced when compared to the wild ones, which demonstrates the effect of ghrelin as an amplifier of GH pulsatility and the supposed role to maintain a certain set-point of IGF1 in the anabolic metabolism. Therefore, ghrelin is not critically necessary for the viability, fertility, growth, appetite, mineral bone density and adipose accumulation and probably is not a direct regulator of leptin and insulin and consequently, ghrelin antagonists are unlikely an anti-obesity solution (10).

The fasting ghrelin level is strongly associated to insulinemia (negative correlation), insulin resistance (negative correlation) and the high density lipoprotein cholesterol levels (positive correlation). Ghrelin suppression induced by food intake is correlated to the postprandial increase in insulin (11).

Ghrelin level is similar in men and women (11) and does not vary with the menopausal status or hormonal substitution therapy, demonstrating that ghrelin level is not regulated by estrogens in women.

Ghrelin and obesity

In humans, ghrelin concentrations double preprandially and decrease to basal values one hour postprandially. In negative energy balance situations such as hypocaloric diets, chronic physical exercises, cancer anorexia, anorexia nervosa and Prader-Willi syndrome, ghrelin concentrations are increased (12). In the obese, ghrelin concentrations are reduced, which can be a result of the important caloric intake, while a weight loss in the obese leads to an increase in ghrelin concentrations. Although ghrelin is increased in patients under certain diets, gastric bypass surgery reduces ghrelin concentrations, suggesting that the size of the stomach can be directly related to ghrelin concentra-

tions.

Ghrelin plasma concentrations evolve in a divergent manner in obesity and anorexia nervosa after dietary intervention, suggesting that ghrelin is a good marker of the nutritional status (13).

Resistance to insulin and hyperinsulinemia are inversely correlated to the ghrelin concentration, which can represent a part of the feedback mechanism that regulates body weight in humans.

A study that has followed the dynamics of ghrelin in obese patients that were subject to a diet for 6 months and in obese patients operated through gastric bypass has shown that the weight loss induced by diet of 17% of the initial weight was associated to a significant increase in ghrelin, demonstrating its role in long-term regulation of body weight. This role is supported by studies on murine models that prove that continuous ghrelin administration increases in a durable manner the body weight (14). Not only does the caloric intake increase, but with the administration of exogenous ghrelin there is also a decrease in the metabolic rate and of the catabolism of fat (14), leading to modifications of all the energy regulation systems that may eventually lead to weight gain. Blocking the cerebral action of ghrelin leads to a reduction in food intake, which suggests that endogenous ghrelin is necessary to maintain a normal appetite. It appears that the increase in ghrelin levels contributes to the adaptive responses that limit weight gain.

In operated patients with a weight loss of 36% of the initial weight, ghrelin level is significantly lower when compared to the obese subjects that represented the controls, as well as when compared to normal-weight subjects. Normal ghrelin fluctuations related to meals and the diurnal secretion rhythm are suppressed after gastric bypass (15). This suggests the role of ghrelin decrease in the weight loss and appetite reduction in subjects operated by gastric bypass, effects that cannot only be explained by the gastric restriction created through the surgical intervention. These patients have a diminished sense of hunger and they spontaneously reduce their intake of high-caloric foods, although they are still capable to appreciate the taste of food. The explication that the authors propose (15) for the decrease in ghrelin levels could be an override inhibition: normally, the absence of nutrients in contact with the gastric mucosa stimulates ghrelin secretion. In the case of gastric bypass, the permanent absence of food in the stomach and duodenum leads to a continuous stimulatory signal that eventually suppresses the production of ghrelin by a process named override inhibition.

Another study (16) has investigated the evolution of ghrelin in obese and anorexia nervosa patients, in obese and normal-weight type 2 diabetics, as well as ghrelin evolution in response to the oral glucose uptake test in normal subjects and to a test meal in diabetics. Ghrelin concentrations were higher in patients with anorexia nervosa and lower in the obese when compared to normal-weight control subjects. Tschop et al. (17) have reported that fasting ghrelin is negatively correlated to the percentage of body adiposity, fasting insulin and leptin concentrations. The study conducted by Shiiya et al. (16) has proven that fasting ghrelin in normal subjects, in those with anorexia nervosa, obesity or type 2 diabetes is negatively correlated to the body mass index of each group. Oral or intravenous glucose administration in normal subjects leads to a decrease in serum

levels of ghrelin, while the administration of a similar volume of water does not, proving that the effect on ghrelin concentration is not related to gastric expansion.

Ghrelin and cachexia

Cachexia is a constellation of symptoms that lead to the wasting syndrome, an increase in the metabolic rate that favors the loss of lean and fat mass and a paradoxical decrease in appetite, persistent in spite of the depleted energy stores. Cachexia appears in the pathophysiological context of various chronic illnesses, such as cancer, cardiac failure, chronic kidney disease and acquired immunodeficiency syndrome. Cachexia is a negative prognostic factor for the underlying illness. In this context, a promising pharmacologic agent is represented by the ghrelin receptor analogue. Ghrelin binds to the GHS-R1a in the cerebral appetite regulatory centers, leading to the increase in expression of Y neuropeptide and agouti-related peptide during short-term treatment. It also presents anti-inflammatory properties, which is even more important when taking into consideration the fact that another factor producing cachexia is the inflammation induced by the initial pathology. In animal studies, the efficacy of GHS-R1a agonists was demonstrated in the treatment of cancer-induced cachexia, chemotherapy and chronic renal disease. Human studies using ghrelin or ghrelin receptor analogues in cancer or cardiac diseases have proven an improvement in appetite and body weight during short-term treatment.

Cachexia is a common characteristic in malignancies, found in up to 85% of the patients with several types of cancer and contributing to over 20% of deaths by cancer, underlining thereby the necessity of an efficient treatment. Weight loss presented by these patients can be severe, with the loss of up to 75% of the lean mass, although even the smallest degrees of weight loss and anorexia are associated to the worsening of prognosis, of the response to chemotherapy and an increased morbidity. Loss of appetite can be a sign of particular importance seeing as in a study on patients with cancer in terminal phases it was proven that the presence of nausea and vomiting is associated to a 68% decrease in survival and contributes to a substantial decrease in the quality of life (18). As in most illnesses associated with cachexia, the presence of underlying inflammation plays an important role in producing cancer cachexia and can represent a target of ghrelin action. Proinflammatory cytokines including IL-1β, IL-6 and TNF-α can be produced by the tumor cells and as well by the host as a response to the tumor. Up to 50% of cancer patients present inflammatory signs at diagnosis and the associated increase in cytokines is involved in the appearance of anorexia, at least partly through its action on the melanocortin central system.

The level of ghrelin was already demonstrated to be increased with approximately 25 % compared to normal values in a variety of cancers associated with cachexia, including pulmonary, breast, colon and prostate neoplasia. Although there may be ghrelin secreting neoplasias, the levels of acyl-ghrelin are 50% higher in cancer patients with cachexia than those without cachexia and 80% higher than in non-cancer patients (19). The presence of anorexia despite higher concentrations of acyl-ghrelin suggests either the presence of a certain resistance to the orexigenic properties of ghrelin in the context of cancer cachexia, or due to the exaggerated anorexi-

genic effects of other processes. The increase of these values can be associated with a saturation of ghrelin receptors, making the pharmacological doses inefficient. Moreover, there is the possibility that these high levels of ghrelin produce unwanted effects such as tumor growth.

The majority of the interventions that administered ghrelin in models of cancer-induced cachexia have shown the improvement of food intake and weight gain, especially due to increase in lean mass. The attempts to treat cancer cachexia with ghrelin have required supraphysiological doses, which have had positive effects on appetite, suggesting that the effect of ghrelin on the appetite regulation centers is not saturated in cancer cachexia. The use of ghrelin and other GHS-R1a agonists on animal models of cancer cachexia has shown a 20-37% increase in food intake, a 10% increase in body weight and a reversal of the losses of lean and fat masses. In humans, the long-term treatment using a GHS-R1a agonist called RC-1291 for a 12-week period has lead to weight gain and increase of the lean mass when compared to placebo (20). However, when measuring the quality of life – important criteria in the treatment of any advanced cancer – there have been no differences between the group treated with the agonist and the placebo group. The problem that is raised is that of the risk of tumor growth that could be stimulated by the increase in GH secretion as a response to GHS-R1a agonists of ghrelin. The study conducted by Garcia (20) has reported a significant growth in the level of IGF1 and IGF1-binding protein 3 in subjects that received the ghrelin receptor analogue compared to the placebo group, without it being clear which type of cancer is more at risk of being developed due to high levels of IGF1. In acromegalic patients with chronic high levels of IGF1, the only more frequently encountered neoplasia is the colonic one.

Another study conducted on 31 patients with progressive, non-responsive gastrointestinal cancers (21) that received low or high doses of ghrelin during an 8-week period has shown that subjects that received high doses reported an increase in appetite, although food intake remained the same. The group receiving high doses of ghrelin presented a decrease in fat mass and a tendency to increase the lean mass, as well as a positive energy balance. Subjects in both groups had a decrease between 9-28% of IGF1, proving that the effect of ghrelin on the body weight can be achieved without an increase in food intake or IGF1 levels.

Ghrelin treatment after the gastric tumor resection has determined a decreased weight loss, although this can be partially due to the replacement of the normal endogenic secretion of ghrelin in the stomach.

Another problem is the possibility that a certain neoplasia might express GHS-R that could respond to the treatment with ghrelin. In a study lead by Wang et al. (22), 51-80% of various types of gastrointestinal cancers expressed GHS-R, but it is unclear whether ghrelin can actually induce tumor growth by stimulating these receptors.

CONCLUSIONS

Ghrelin is a recently-discovered hormone with essential effects on the nutritional status. The understanding of its physiology can help explain the disturbances found in several nutrition-related pathologies and can support the development of therapeutic possibilities using ghrelin or its analogues.

OBESITY - RISK FACTOR FOR CARDIOVASCULAR DISEASES (Abstract): Infantile and juvenile obesity is a medical, social and cultural problem, which reaches epidemic proportions worldwide. In Romania, according to the World Health Organization, one out of four Romanians is obese. As far as infantile obesity is concerned, Romania ranks third in Europe. Infantile obesity has a major impact on all body systems and is associated with risk factors for cardiovascular diseases and accelerated atherosclerotic processes, including hypertension, atherogenic dyslipidemia, atherosclerosis, metabolic syndrome and functional and structural cardiac changes. **Aims:** To study the cardiovascular complications of the obesity at children and adolescents. **Material and methods:** Our study was conducted on a group of 188 obese and overweight patients that were hospitalized in the Pediatric Cardiology Department, the "Sfânta Maria" Children's Hospital of Iaşi between 1 January 2006 and 1 January 2011. The patients' evaluation was based on: anamnesis, clinical criteria and paraclinical criteria. **Results:** The distribution of cases by age group was the following: 51% of patients were aged 7-13 years, 42% were teenagers and only 6% of patients were aged between 2-6 years. As far as the patients' origin is concerned, we noted that 58% of them lived in urban areas. In the study group, 21% of the subjects had borderline hypertension, while 16% of them suffered from definite hypertension. The echocardiogram that was performed on all the patients included in the study revealed hypertrophic cardiomyopathy in 12% of the patients. **Conclusions:** Child obesity has a major impact on all the big body systems and it is known to contribute to significant increases in the mortality and morbidity rates. **Keywords**: OBESITY, CARDIOVASCULAR COMPLICATIONS, HYPERTENSION, METABOLIC SYNDROME.

Infantile and juvenile obesity is a medical, social and cultural problem, which reaches epidemic proportions worldwide.

Children whose body mass index are equal to or exceeds 95 percent are considered obese, whereas those whose body mass index ranges between 85 and 95 percents are referred to as overweight (1, 3).

The worldwide prevalence of overweight and obesity in children and adolescents increased considerably from 4.2% in 1990 to 6.7% in 2010. The infantile obesity prevalence is expected to reach 9.1% (about 60 million) in 2020. According to the data collected in 144 countries in 2010, about 43 million pre-school children (of whom 35 million in developed countries) were obese or overweight, while 92 million ran an overweight risk. The infantile obesity prevalence was 8.5% in Africa in 2010, and it is expected to reach 12.7% in 2020. This prevalence was low in Asia, in 2010, as it reached a mere 4.9%, yet the number of concerned children was higher (18 mil-

lion). In America, between 16 and 33% of the children and adolescents are obese (1,2).

In Romania, according to the World Health Organization, one out of four Romanians is obese. As far as infantile obesity is concerned, Romania ranks third in Europe.

Infantile obesity has a major impact on all body systems and is associated with risk factors for cardiovascular diseases and accelerated atherosclerotic processes, including hypertension, atherogenic dyslipidemia, atherosclerosis, metabolic syndrome and functional and structural cardiac changes (1).

Infantile obesity causes the occurrence of the atherosclerotic disease in the child's vascular structures, which affects especially the aorta and coronary arteries.

Owen et al. argue in their study that the body mass index during childhood is closely related to later cardiovascular disease risks (1, 4).

MATERIAL AND METHODS

Our study was conducted on a group of 188 obese and overweight patients that were hospitalized in the Pediatric Cardiology Department, the "Sfânta Maria" Children's Hospital of Iaşi between 1 January 2006 and 1 January 2011.

The patients' evaluation was based on:

- Anamnesis: which included questions related on the patients' age, gender, origins, family history of various diseases (close family diagnosed with obesity, hypertension, diabetes mellitus), personal physiological history (small weight at birth, food received during the first months of life, diversification) and personal pathological history (genetic syndromes, endocrine diseases, dyslipidemia, diabetes mellitus). Emphasis has been placed on the child's feeding habits, on investigating possible psychological causes of hyperphagia (separation from parents of the latter's leaving abroad to work), and also on the child's lifestyle (practicing different forms of physical activity).
- Clinical criteria: anthropo-metric data (weight, body mass index), arterial tension and heart rate measurement, pulse determination, identification of symptoms of headache, tinnitus, dizziness.
- Paraclinical criteria: haematological checks (glycemia, total lipids and cholesterol dosing, lipid profile), electrocardiogram, Holter monitoring of arterial tension and Holter – EKG monitoring (of patients with high arterial tension values or altered electrocardiogram), echocardiogram, ophthalmological examination, genetic examination, endocrine examination, neuropsychiatric and psychological examination, consult nutritional diseases.

RESULTS

The distribution of cases by age group was the following: 51% of patients were aged 7-13 years, 42% were teenagers and only 6% of patients were aged between 2-6 years (fig. 1, 2).

As far as the patients' origin is concerned, we noted that 58% of them lived in urban areas, which is attributed to sedentary as well as eating fast food.

Here is the case distribution over the five years of study: 24% of the cases in 2006, 16% in 2007, 30% in 2008, 10% in 2009 and 20% in 2010 (fig. 3, 4).

Study of anthropometric indices (weight, height, body mass index) showed that 63% of patients in the study were obese (BMI greater or equal than percentile 95) while 37% were overweight (BMI of between 85

and 95 percentiles). When case distribution according to gender was considered, we noted a higher obesity rate in the female sex (59%) than in the male sex (41%).

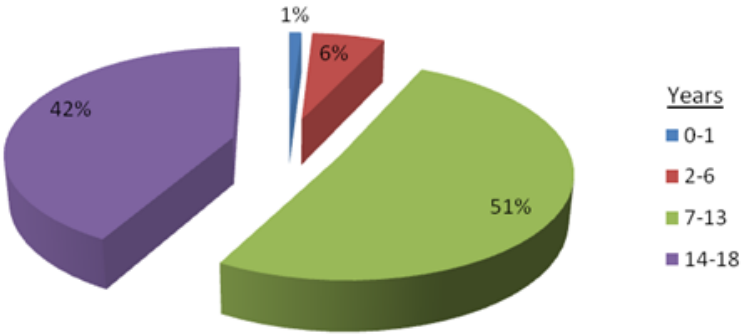

Fig. 1. Case distribution on age groups

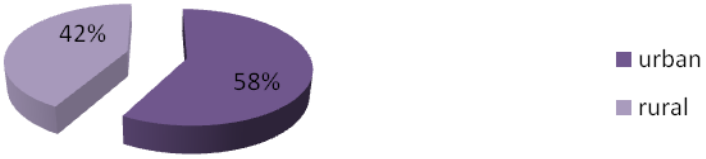

Fig. 2. Case distribution to the patients' origin

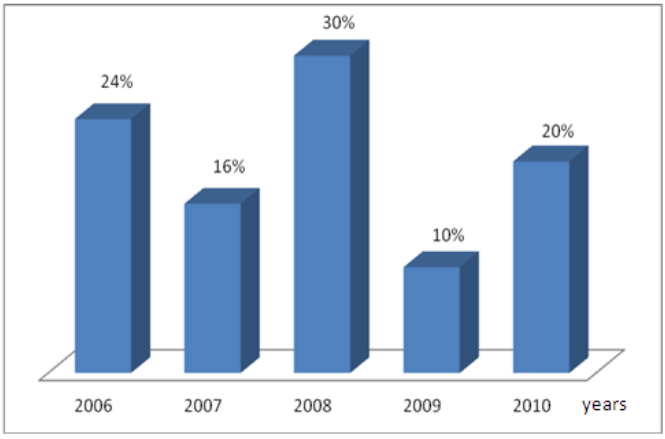

Fig. 3. Case distribution over the years studied

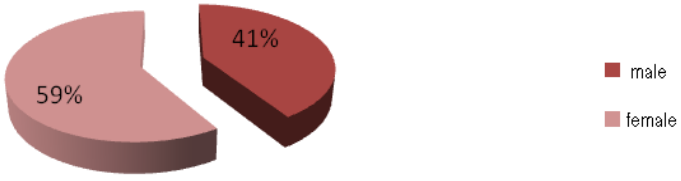

Fig. 4. Case distribution according to sex

The analysis of the data gathered during anamnesis revealed the 33% of the patients had a personal history of various diseases, and 34% of the subjects had immediate family members suffering from arterial hypertension, diabetes mellitus or obesity.

35% of the patients came to the hospital since they experienced specific symptoms such as dyspnoea on effort, tinnitus, headache, dizziness or high arterial tension values detected in the outpatient clinic.

In the study group, 21% of the subjects had borderline hypertension, while 16% of them suffered from definite hypertension (fig. 5).

Another criterion considered was modification of the ECG. Of the 188 patients included in the study group, 10% had sinus tachycardia, 2% had extrasystolic arrhythmia, 5% had sinus arrhythmia, 7% had atrioventricular conduction diseases and 6% had biventricular overstrain.

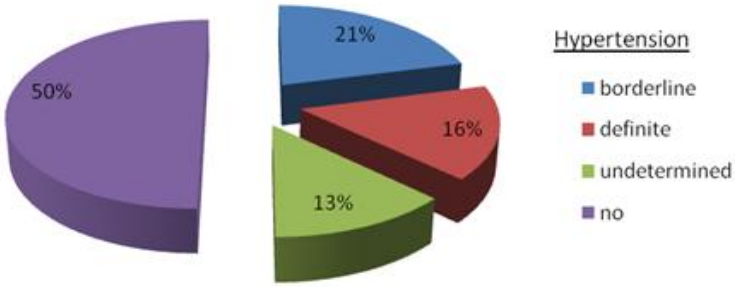

Fig. 5. Case distribution depending on hypertension presence

The ophthalmological examination performed revealed fundus of the eye changes in 5% of the cases, of whom 4% had retina vessels with increased spasticity and only 1% suffered from 1st or 2nd degree hypertensive retinopathy.

One of the diagnosis criteria was the detection of connections between hypertension and fundus of the eye changes. Of the 188 patients, 5% exhibited such connections, 6% suffered only from hypertension and had no fundus of the eye changes, whereas 89% of them did not exhibit such an association.

The echocardiogram that was performed on all the patients included in the study revealed hypertrophic cardiomyopathy in 12% of the patients (fig.6).

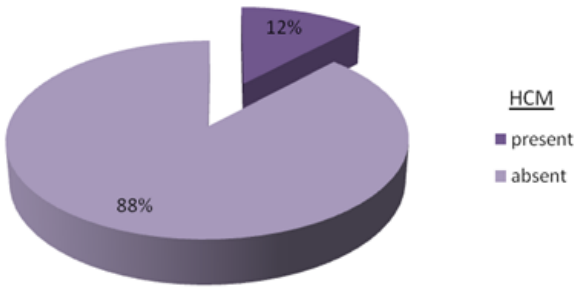

Fig. 6. Case distribution according to the presence of HCM

8% of the patients in the study group associated hypertension and high cholesterol levels, 16% of them had high blood pressure values yet their cholesterol levels were low and 5% of the patients had high cholesterol levels but no hypertension (fig. 7).

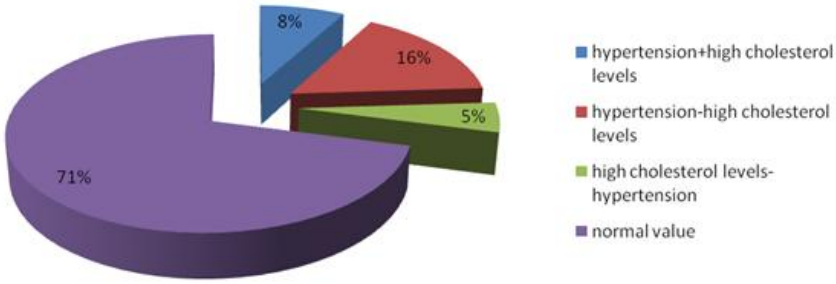

Fig. 7. Case distribution according to the association between hypertension and high cholesterol levels

4% of the children in the study group associated high blood pressure values, high cholesterol levels and hypertrophic cardiomyopathy (fig. 8)

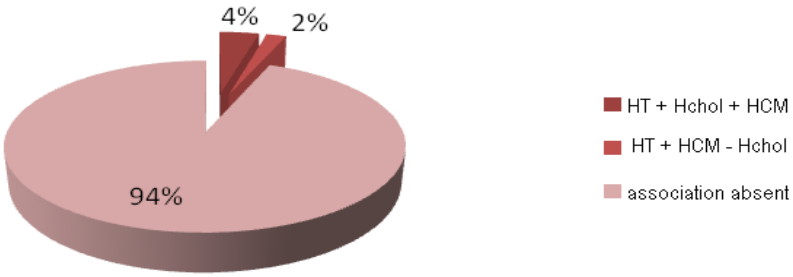

Fig. 8. Presence of an association between HT + high cholesterol levels +HCM

The psychological and neuro-psychiatric exams carried out revealed that 1% of the 188 studied patients came from over-protecting families, 4% had suffered psychological trauma in their personal history (parents' divorce/separation), 2% of the subjects suffered from the Italia syndrome, 18% encountered social and family integration difficulties and 14% had a luminal intellect.

DISCUSSION

Child obesity has a major impact on all the big body systems and it is known to contribute to significant increases in the mortality and morbidity rates (1,5).

The data gathered so far suggest that atherosclerotic cardiovascular processes commence in early childhood and are influenced over a person's life by both genetic and modifiable risk factors such as exposure to harmful environmental factors, including obesity (1,6).

According to literature, the obesity rate is higher in pre-school and adolescent children (1,2). The infantile obesity rate has increased twice in pre-school children aged between 2 and 5 and in adolescents be-

tween 12 and 19 years of age, and 3 times in 6 to 11 year-old children, over the last three decades. Although the obesity rate is higher in females, the male sex has a higher risk of cardiovascular diseases (1).

High blood pressure values (AT>95%) were detected in 35.4% of the overweight children by a study conducted in Europe (1,8). The data collected by a study conducted in India, on a group of 25000 of school children aged between 5 and 16 years revealed a similar percentage (1,7). In our study, high blood pressures were identified in 10.10% of the normal weight children, in 17.34% of the overweight children and in 18.32% of the obsess children (1).

Hypertension and obesity are connected most of the times and they put double pressure on the left ventricle, thus leading to the occurrence of both dilation and muscular hypertrophy (13).

In left pathological ventricular hypertrophy, the increase is not proportional, and the ventricular function is altered, the coronary vessel dilating capacity is reduced and the process regression is impossible (12). Obese subjects are 4 times more likely to suffer from compensatory left ventricular hypertrophy associated with low ejection fraction, reduced myocardial contractility and the need of the left atrium to have more force to fill the left ventricle (11). Concentric remodelling was the most common in obese children, whereas concentric hypertrophy was especially characteristic of those who also suffered from hypertension (13).

In their study, Li et al. performed echocardiograms of 467 young people and reported that a high body mass index during childhood, obesity and systolic hypertension during adulthood, as well as the cumulated burden of obesity and systolic hypertension from childhood up to adulthood are predictive factors of left ventricle muscle mass increase in young adults (10). Ventricular hypertrophy has higher prevalence in obese (33.5%) and overweight (12.4%) children as compared to normal weight children (3.5%). In a study, the patients with borderline hypertension were found to have higher left ventricle muscle mass values than those with normal tension values (13). Obesity, hypertension and concentric hypertrophy are independent predictors of diastolic dysfunction. 52% of the obese children in our study had hypertension, which means that their body mass index, left ventricle dimensions and left atrium muscle mass index were also high. These subjects also exhibited diastolic function changes.

42% of the patients had concentric remodeling (muscular dilation) and 32% of them suffered from concentric hypertrophy, which supports a strong association between hypertension and ventricular remodeling. Previous studies have shown that an excess of body mass is associated with high blood flow values and eccentric hypertrophy. Nevertheless, only 6% of the subjects in our study suffered from such conditions, as most of them exhibited muscular dilation and concentric hypertrophy (13).

On the other hand, cardiovascular diseases, be they inborn or acquired, cause increased obesity prevalence, given the limited physical activity recommended by the cardiologist or preferred by the family or even the patient. A vicious circle is thus created in which obesity worsens heart conditions and lack of physical activity due to heart conditions accentuates obesity (14).

CONCLUSIONS

Our research conducted on the study

group described above enabled us to conclude that high overweight and obesity rates are especially characteristic of the 7-13 years age group. The incidence of obesity is much higher in the urban (58%) than in the rural areas, which is due to the unhealthy fast food available in urban areas. The incidence of obesity is higher in the female (59%) than in the male sex. 37% of the patients suffered from hypertension, 21% of whom had borderline hypertension and 16% suffered from definite hypertension. Changes in the fundus of the eye associated to hypertension were revealed in 5% of the patients, while hypertrophic cardiomyopathy was detected in 12% of the study subjects. 8% of the subjects associated hypertension and high cholesterol levels, and 5% had high cholesterol levels but no hypertension. Only 4% of the subjects associated high blood pressure values, high cholesterol levels and hypertrophic cardiomyopathy.

RESEARCH ON AROMATASE GENE (CYP19A1) POLYMORPHISMS AS A PREDICTOR OF ENDOCRINE THERAPY EFFECTIVENESS IN BREAST CANCER

L. Miron[1], L. Negură[2], D. Peptanariu[2], M. Marinca[1]

2. Discipline of Immunology

RESEARCH ON AROMATASE GENE (CYP19A1) POLYMORPHISMS AS A PREDICTOR OF ENDOCRINE THERAPY EFFECTIVENESS IN BREAST CANCER (Abstract): Single nucleotide polymorphisms (SNPs) of the CYP19A1 gene have shown the ability to modify its activity, but no association has been established with aromatase inhibitor (AI) efficiency in hormone receptor positive breast cancer (BC). **Material and methods**: The study included blood samples from 53 patients (p) with BC and 1 control (male DNA); 22p. (investigational group) were administered an AI and followed up. **Results**: Homozygous (hh) – CC and TT –, and heterozygous (hz) – TC – genotypes of the rs10046 SNP were balanced. Response to treatment or progression were not affected (p=0.630) in patients with T allele 1**;** local relapse occurred significantly more rarely and overall survival (OS) was superior (p=0.046). For rs4646, genotypes were mainly hhGG (57%), with no implication to study parameters (p>0.05). For rs727479 SNP, major genotypes were hhTT (40%) and hzTG (45%). Therapeutic response was better in patients with T allele 2 (p=0.040), T allele 1 was associated with reduced local recurrence (p=0.047) and TT genotype with better OS (p = 0.008). In rs700518 SNP, genotype was mostly hzGA (49%). Local recurrence rates were reduced in the presence of G allele 1 (p=0.047) and GG homozygosity. **Conclusions**: At this stage, the study was purely exploratory and hypothesis generating. Genotyping of at least three of the four CYP19A1 SNPs evaluated (except rs4646) may have an impact in clinical practice, providing better criteria for patient selection, prognosis and therapeutic decision in BC.
Keywords: BREAST CANCER, AROMATASE INHIBITORS, CYP19A1, GENETIC POLYMORPHISMS.

Breast cancer (BC) is the most common female neoplasia (crude incidence 109.8/ 100000/year in the EU), and the leading cause of cancer death (38.4/ 100000/year), mostly by metastatic disease. Treatment options in BC are systemic chemotherapy (aggressive disease but good performance status), targeted biological agents such as trastuzumab and lapatinib (HER-2/*neu*-positive tumors) and hormone therapy (non-visceral metastases); about 50-55% of breast tumors are hormone-dependent (1).

Estrogens exert their physiological effect after binding of two specific nuclear proteins: estrogen receptors (ER) alpha (predominant in the mammary gland and reproductive tract) and beta. Estrogen-receptor complexes (ERCs) form homodimers and

interact with specific elements in promoter regions of responsive genes in target cells, and further with transcription factors, such as co-activator proteins of the steroid receptor (SRC, p160), initiating the production of mRNA and increased protein synthesis in the endoplasmic reticulum. Resulting enzymes, receptors, and secretory factors are involved in regulation of various cell functions, growth and differentiation. Thus, estrogen induces and/or promotes proliferation of certain target cells (mammary epithelium, but also estrogen-dependent malignant cells), as demonstrated on several experimental BC cell lines (MCF-7, T47D, ZR-75-1) (2).

For these reasons, endocrine therapy is a major therapeutic option in ER-positive BC patients. While tamoxifen remains the standard therapy for premenopausal women, third generation aromatase inhibitors (AI) (non-steroidal: anastrozole, letrozole, or steroidal: exemestane) are the preferred first-line treatment in postmenopause (3, 4).

Aromatase (also known as estrogen synthase) is a 58-kDa monoxigenase belonging to the cytochrome P450 superfamily of enzymes, which converts androgens (testosterone and androstenedione) to estrogens (estradiol and estrone, respectively). Its activity is modulated through tissue-specific promoters (PI.1, PI.3, PI.4, PI.6, PI.7, PII), hormones, cytokines; it increases with age, body weight, alcohol, decreases due to smoking; it may be induced by clonidine, dexamethasone, insulin, diethylstilbestrol, phenylephrine, and inhibited (besides AI) by clomiphene, dopamine, antifungal drugs, oxycodone, paclitaxel, tamoxifen or trastuzumab. The gene that encodes aromatase is called CYP19, has two transcriptional variants (A1 and A2) and is located on chromosome 15q21.1. Mutations could lead to both inhibition and stimulation of its expression (5).

MATERIAL AND METHODS

Our study included a total of 53 histologically-confirmed BC patients, from which informed consent was obtained for the collection of peripheral blood to assess the four selected polymorphisms of the aromatase gene (CYP19A1). Full details of each sample (collection date, blood volume, anticoagulant, name, code number) were recorded for DNA collection. The patients had a mean age at diagnosis of 55.09 years (range 36-72 years). All were hormone receptor-positive (ER expression: 5-95%, progesterone receptor, PR: 0-100%), and more than half (54.5%) were Her2/*neu* negative; as such, 68.2% of cases were assigned to the luminal A and B molecular subtypes (1-4). Radiotherapy indication, schedule and dosage were not modified in any way by participating in the study. Therapy was well tolerated in all cases, and there were no major toxicities. Average survival for the whole patient sample was 4.95 years (range 1.6 to 17.4 years). CYP19A1 single nucleotide polymorphism (SNP) genotyping was performed by allelic discrimination in the Taqman system using the Applied Biosystems 7500 Real-Time PCR System. To assess potential clinical significance of SNPs considered of interest, we followed the response to hormone therapy (including an aromatase inhibitor, AI) and other anticancer therapies, and survival parameters (overall survival, OS; disease-free survival, DFS; time to progression, TTP) for a group of 22 investigational patients diagnosed with BC in the records of the "St. Spiridon" Hospital Oncology Outpatient facility. Significance of correlations between dif-

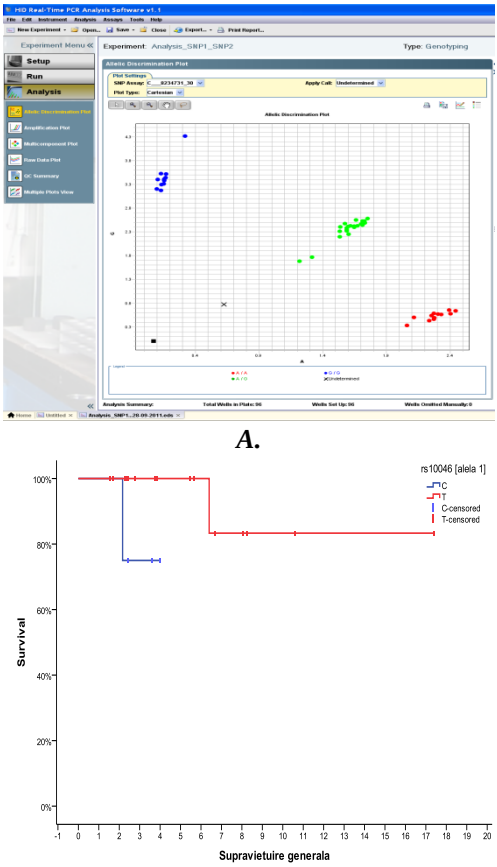
ferent SNPs, clinical parameters, and those involving time-dependent variables, was evaluated by chi-square tests and two-sided log-rank tests, respectively.

RESULTS

A. Genotyping of the rs10046 polymorphism (CYP19A1 c.1531C> T). Of the 53 BC patients and 1 control (DNA from a male) genotyped for this SNP, 14 were homozygous (hh) CC genotype (26.5%), 14 hhTT (26.5%), and 25 heterozygous (hz) TC (47%), as well as the control. Frequencies were identical, 50% (53/106) for C and T alleles, and their allelic distribution in the study group was very well balanced (fig. 1.A).

The distribution of alleles in the investigational group (22 patients) was also balanced: 22.7% with hhTT genotype (5/22), as compared with 18.2% for the hhCC genotype (4/22), and 59.1% for hzTC (13/22). T allele was present in 52.3% of studied haplotypes, while the ancestral allele C in the remaining 47.7%.

Response to treatment was not significantly influenced by any of the genotypic variants (p=0.630), although the presence of T allele (especially homozygous) appeared to associate with a lower rate of progression after first line treatment. When AIs were administered, local recurrence occurred significantly less frequently in patients who had a T allele 1, and nodal recurrence in those with T allele 2 (p=0.047); pattern of metastasis was not altered by genotype. The response to second line treatment also appeared better (p=0.503) for homo-and heterozygous T variants, this allele showing a trend for negative prediction of relapse in this situation (p=0.082). DFS did not correlate with this SNP, but TTP is potentially improved in patients with a T allele 1 (p=0.070). On the other hand, a T allele 2 (and possibly hhTT genotype) was prognostic for relapse as unresectable metastatic disease, meeting statistical significance criteria in patients not receiving an AI (p=0.046), while the presence of T allele 1 predicted a superior OS (p = 0.046) in patients treated with an AI (fig. 1.B).



A.

B.

Fig. 1.A. Allelic discrimination plot for rs10046 SNP (hhCC: blue, upper left; hhTT: red, lower right; hzTC: green, middle). **B.** Significant OS improvement (p=0.046) for T allele 1.

B. Genotyping of the rs4646 polymorphism (CYP19A1 c.1673T> G). Of the 53 patients analyzed, 30 were hhGG (57%), 6 hhTT (11%) and 17 had hzTG profile (32%). The control (DNA from a male) had the GG genotype. Allele frequencies in the study group were 27% for T allele (29/106), and 73% for the ancestral G allele (77/106) (fig. 2), which has been previously associated with increased ER levels in postmenopausal women. In the investigational group, rs4646 SNP allele distribution was extremely unbalanced, 63.6% of patients presenting hhGG genotype (14/22); no patient in this subset was genotyped as hhTT. T allele was present in 18.2% of studied haplotypes, and the ancestral G allele in 81.8%. Response to first line treatment and relapse rates were not affected by rs4646 SNP (p=0.933, p=0.746). Second line endocrine therapy had better results in genotype TG patients (p=0.050) treated with an AI, but OS, DFS and TTP did not correlate with this SNP (p>0.050).

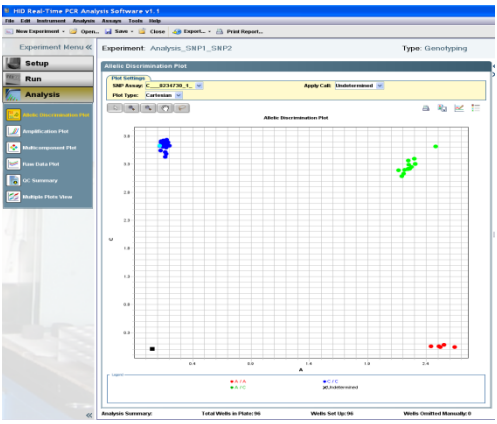


Fig. 2. Allelic discrimination plot for rs4646 SNP (hhGG: blue, upper left; hhTT: red, lower right; hzTG: green, middle).

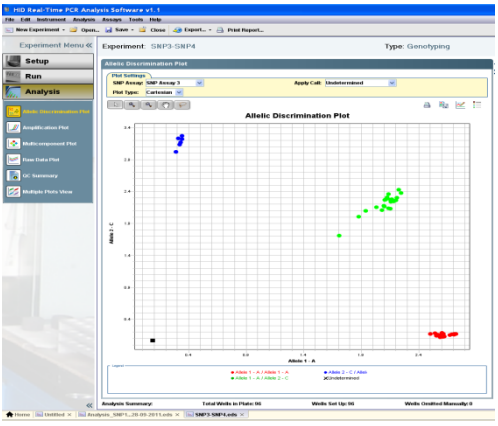
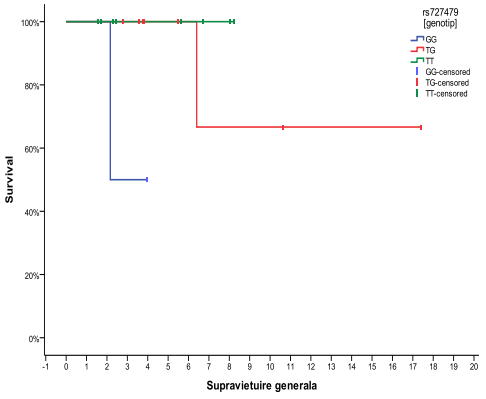
C. Genotyping of the rs727479 polymorphism (CYP19A1 418 c.145 G> T). Fig. 3.A. shows the allelic distribution plot for the 53 patients: 8 were hhGG (15%), 21 hhTT (40%), and 24 (plus the control) hzTG (45%). Allele frequencies in the study group were 38% for G (40/106), and 62% for the ancestral T allele (66/106), and in the 22-patient study subgroup: 65.9% T, 34.1% G; 63.6% hhTT genotype (14/22), and only 9.1% hhGG (2/22).



A.



B.

Fig. 3.A. Allelic discrimination plot for rs727479 SNP (hhGG: blue, upper left; hhTT: red, lower right; hzTG: green, middle). **B.** Association of hhTT genotype with better OS (p=0.008)

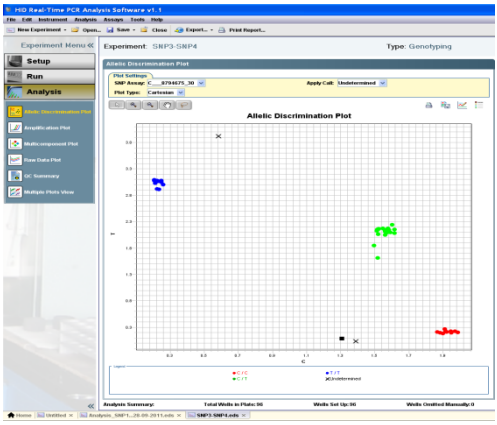
Therapeutic response (first line) was significantly better in patients with a T allele 2 (p=0.040), apparently higher in those treated with an AI (p=0.099); most cases with progressive disease were genotyped GG or TG. The same relationship with the relapse rates has seen a trend towards significance (p=0.099).

T allele 1 was associated with reduced local recurrence (p=0.047) and TT genotype with the much less frequent appearance of visceral metastases (p=0.013) in patients treated with upfront AI. DFS had a trend of positive correlation (p=0.072) with the presence of T allele 2 in patients treated with AIs. The T allele 2 and the hhTT genotype have anticipated a better DFS (p=0.011, and p=0.040 respectively), possibly a longer TTP (p=0.052) after second line treatment, and were strongly associated with better OS (p=0.003, and p=0.008) (fig. 3.B).

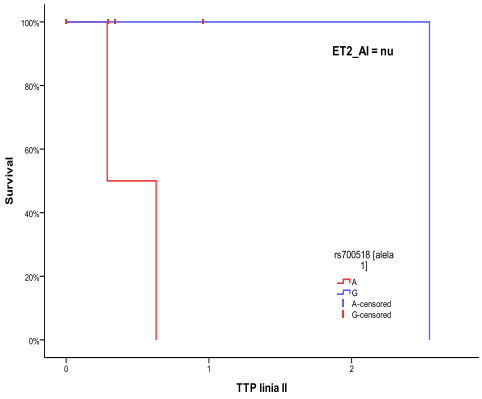
D. Genotyping of the rs700518 polymorphism (CYP19A1 c.1673T> G). A balanced distribution of alleles was observed in the main group (53 patients+1 control). The hhAA genotype was identified 14 times (26.5%), while the opposite GG appeared 13 times (24.5%); most patients (26/53) were genotyped as hzGA (49%), as was the control. At the allelic level, 50.9% of cases (54/106) were A, and 49.1% (52/106) were G (fig. 4.A).

The alleles of SNP rs700518 (A and G) were perfectly equal in the investigational subgroup. 22.7% patients (5/22) had hhAA genotype, 22.7% (5/22) hhGG, and 54.5% (12/22) hzGA.

In this group, treatment response was not influenced by rs700518 genotype (p=0.686), but local recurrence rates were low in the presence of a G allele 1 (p=0.047) and/or GG homozygosity in patients treated with upfront AI. DFS did not correlate with polymorphism, while TTP appeared higher in patients with a G allele 1 (p=0.070), regardless of the use of AI. Statistical significance was reached for TTP improvement in the presence of a G allele 1 (p=0.035), but particularly in patients not treated with an AI (p=0.046). This also appeared to influence OS, but not clearly enough (p=0.083) (fig. 4.B).



A.



B.

Fig. 4.A. Allelic discrimination plot for rs700518 SNP (hhAA: blue, upper left; hhGG: red, lower right; hzAG: green, middle). **B.** Significant TTP improvement (p=0,046) in patients not treated with an AI, in the presence of G allele 1.

DISCUSSION

In the molecular and genomic era, BC is a topic of urgent research. Currently, the role of stem cells, circulating tumor and endothelial cells, and that of nucleic acids, mRNA and miARN in progression and metastasis are under scrutiny; multiple multigene "signatures" have been developed, functional imaging methods for hormone receptors and HER-2/*neu* were imagined, interactions of estrogen signaling pathways with mechanisms of angiogenesis, apoptosis or EGFR/HER were highlighted (6-12).

Although AIs yielded superior clinical outcomes as compared to tamoxifen in terms of response rates, time to progression and (for letrozole) survival, also with a favorable toxicity profile, the results are relatively inconsistent (13). Also, to our knowledge there are currently no direct comparative studies between the 3 commercially available AIs. Moreover, in current clinical practice, the indication for use of AIs in these patients is generally guided by only two clinical-pathological criteria: postmenopausal status and hormone receptor positivity (with little relevance to their quantification, given the mechanism of action different from SERMs). Thus, the ability to discriminate between AI-responsive and non-responsive patients is low, but genetic and epigenetic factors that affect metabolism, efficacy and safety of medication may be of particular importance (14).

The role of the CYP450 system was clearly proved important in the metabolism of tamoxifen – although this information has not been incorporated into routine practice, 7-10% of women with ER-positive BC harbor CYP2D6 mutations involved in resistance to tamoxifen. While AIs are gaining momentum as first-line endocrine treatment in BC, the role of CYP19A1 – although essential in the metabolism of AIs – is much less studied so far. Polymorphisms (single nucleotide polymorphisms, SNPs) of the CYP19 gene have demonstrated the ability to change aromatase activity (and that of its inhibitory drugs) in postmenopausal women (5,15,16). However, although some studies have investigated the association between CYP19 SNPs and the risk of BC (17,18), to date, only one study (16) analyzed the CYP19 SNPs in relation to prognosis of BC patients treated with letrozole. No association between CYP19 genotype and efficiency of AIs is evident at this time. Associations of CYP19 variants with BC risk targeted only certain SNPs, found in most studies in this field. These include repeat polymorphic variants $[TTTA]_n$, of which allele $[TTTA]_7$ was observed with a relatively high frequency in BCs of the Caucasian population. Also, the silent exon 3 version Val80Val (rs700518) was observed in incomplete linkage disequilibrium with $[TTTA]_7$. Other candidate alleles related to the risk and the evolution of BC, although inconsequently, were: $[TTTA]_7$delTCT, $[TTTA]_{>10}$, $[TTTA]_8$, $[TTTA]_{10}$, $[TTTA]_{11}$ and $[TTTA]_{12}$. Associations were observed between some of these alleles and serum concentrations of circulating metabolites associated to estrogen, which justify genotyping of the region affected by the above-mentioned repeats also for their association with treatment response. Most studies have considered two SNPs of the 3'-UTR non-translated region (rs10046 and rs4646), and one located in the intronic region (rs727479), seemingly the most obvious candidates for an analytical study (19,20). Corresponding SNP alleles $[TTTA]_7$ and $[TTTA]_{<9}$ were associated with low estrogen levels, while the

$[TTTA]_8$, $[TTTA]_{>9}$, rs727479, rs10046 and rs4646 were associated with a high level of the hormone. The Val80Val allele (rs700518) was associated with an increased expression of aromatase.

In this context, CYP19 SNP genotyping may be regarded as a potential predictive factor for response to AI treatment of breast tumors. Identifying the prevalence and location of these alterations or simple genetic variants may allow individualization of systemic therapy based on tumor characteristics, and also host genetics, influencing therapeutic efficacy and safety in BC. The limits of this study lie in the small number of cases, and the results and methods used need additional research and external validation. These results should be therefore looked upon with caution, and p-values are given only for illustration of the apparently emerging correlations.

CONCLUSIONS

At this stage, our research was purely exploratory and hypothesis-generating from a clinical point of view, while it was mainly aiming to perfect and standardize the laboratory techniques used. However, we may conclude that genotyping of at least three of the four polymorphisms of the CYP19A1 gene evaluated by us (except rs4646), and possibly others, might have an impact on clinical practice, by providing better criteria for patient selection, prognosis and therapeutic decision in locally advanced, hormone receptor-positive BC.

NEWS

ROLE OF MASP-1 IN LECTIN PATHWAY ACTIVATION

The activation of lectin pathway of complement is thought to occur due to recognition of pathogens by MBL (mannan-binding lectin) in complex with MASP-2 (MBL-associated serine protease), followed by cleavage of C4 and C2. Related proteases such as MASP-1 and MASP-3 are central to alternative pathway function in mice, by activation of profactor D and factor B. Also, MASP-1 plays a role in MASP-2 convertase generation, through C2 auxiliary cleavage. A study by Degn *et al*. on a patient deficient in MASP-1 and MASP-3, shows that MASP-1 is crucial for complement activation, since it was able to restore the nonfunctional lectin pathway which the patient had. MASP-1 increased lectin pathway activity through direct activation of MASP-2. MASP-1 and MASP-2 can associate in the same MBL complex and such complexes can be found in serum, meaning that MASP-1 and MASP-2 act analogous to C1r and C1s of the classical pathway. Degn SE, Jensen L, Hansen AG et al. Mannan-Binding Lectin-Associated Serine Protease (MASP)-1 Is Crucial for Lectin Pathway Activation in Human Serum, whereas neither MASP-1 nor MASP-3 Is Required for Alternative Pathway Function (*The Journal of Immunology*, 2012; 189 (8): 3957 DOI: 10.4049/jimmunol.1201736).

DYADIC ADJUSTMENT IN HIV SERO-CONCORDANT AND SERO-DISCORDANT COUPLES (Abstract): **Aim**: The HIV infected population in Romania is at an age when engaging in a serious relationship is more and more an issue. Dyadic adjustment is the process which most couples go through, in their attempt to form a steady relationship. It is represented by important changes that appear in one's perception of himself and the significant other. Dyadic adjustment can be measured by a series of parameters – couple's satisfaction, couple's consensus, couple's cohesion and expressing emotions. **Material and methods**: We conducted a study on 60 young men and women (30 male, 30 female). Of these, 45 are in evidence at the Iași Regional Center (22 male, 23 female), the other 15 being their uninfected parteners (8 male, 7 female). They were evaluated using the Dyadic Adjustment Scale, developed by Graham B. Spanier. **Results**: Most couples enrolled in this study (50%) were sero-concordant (both partners were HIV-positive –15). 26% of couples were made-up an HIV-positive female and a non-infected male, and 24% were made-up of a non-infected female and an HIV-positive male. The median age was 23 years, 33.4% of them came from rural areas. Average schooling level was 6 primary classes, with extremes between two classes of primary and higher education. Only 50% of patients had a job, while the rest had no stable job and were not employed, 33.4% came from broken families or foster care. 100% of HIV infected patients are in active therapy, poliexperimented. Most patients have 5-6 treatment regimens (45%), with a maximum of 8-9 regimens. Most of the couples enrolled (83.3%) were not married, as our study evolved only 5 married couples. The relationship length varied between 4 moths and 15 years. The Dyadic Adjustment Scale revealed high scores in couple's consensus and cohesion for both concordant and discordant couples. In couples where both partners are HIV-positive, the DAS revealed average scores for all four areas of dyadic adjustmet. In Couples where one partner is HIV-positive, and the other is not infected, low scores were seen in emotional expression and in the couple's satisfaction. **Conclusions**: The HIV infection affects an individual's life and his adjustment to a couple in the sense that a series of factors changes the couple's dynamic – physical and emotional changes specific to the infection and AIDS, ARV treatments' side-effects, the care for the uninfected partner, and preventing HIV transmission through intercourse. All these elements lower the level of dyadic adjustment and increase the level of stress in individuals that are part of an HIV couple. **Key words**: HIV, SIDA, SIDE-EFFECTS, INFECTED COUPLES.

While recent scientific efforts have resulted in a series of discoveries and advances in understanding and controlling the virus that causes AIDS, this progress has

had limited impact on the majority of HIV infected people and populations living in developing countries. The social and economic conditions that nurture the spread of the virus have to be confronted as essential elements in local and global efforts to stem its spread and create effective solutions to halt the epidemic. They must also be considered in supporting and improving the quality of life of the infected people (1, 12).

The specifics of the adolescent and youth HIV infected population in the Moldova area have been widely discussed. If in the past taking care of the HIV infected person was the duty of the infectious diseases doctor and the patient's family, today the idea of a whole team of specialists working together is becoming increasingly popular. Also the focus has shifted from "taking care" of the patient to helping and supporting him in living a full and normal life. The psychologist's role is more clearly defined, as well as the implications of the social worker. And more importantly, a large number of doctors from different fields are becoming more and more involved and open-minded about treating this type of patient (5, 6).

The mentality of the population in general is also changing. The speed of this change differs from country to country, and in Romania accepting new ideas is not done at a fast pace. However, people are becoming increasingly more aware of different aspects that involve their everyday safety and this includes correct information about being infected with HIV and developing AIDS. This reflects in engaging in sexual contact and forming a couple with an HIV-infected person.

Even though the F type HIV that is the main cause of infection in our country has, so far, allowed a longer than expected life span, the young infected people have grown up with the knowledge that the disease they have is a chronic one, that allows them to do sometimes less than a healthy individual. However, the social and psychological support that they have had since childhood has so far created strong personalities, that can take care of themselves and may in fact have a normal life, going through all the stages of social development (6, 10, 16).

For adolescents and youth, it is difficult to build a life on a foundation that is still unsure and filled with past and current frustrations about discrimination and being different.

Growing up with AIDS has not been and is not an easy task. This explains many young people's desire to live their life on a more accelerated rate than post persons do.

One of the main characteristics of HIV infected youth is their tendency to fall in love and want to get married early, their acute desire to have children, and enjoy all the positive aspects of life "as soon as possible"(1, 4, 15).

Dyadic adjustment is the process which most couples go through, in their attempt to form a steady relationship. It is represented by important changes that appear in one's perception of himself and the significant other. Dyadic adjustment can be measured by a series of parameters – couple's satisfaction, couple's consensus, couple's cohesion and expressing emotions.

MATERIAL AND METHODS

The study was conducted on 60 young men and women (30 male, 30 female). Of these, 45 are in evidence at the Iaşi Regional Center (22 male, 23 female) as being infected with HIV/AIDS, the other 15 being their uninfected partners (8 male, 7 female).

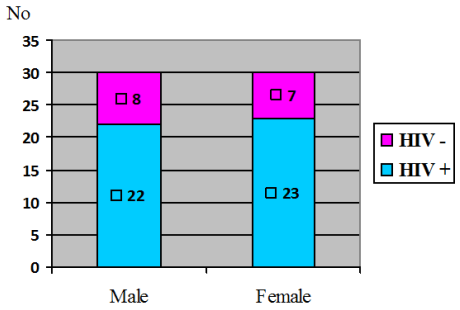

Fig. 1. The subjects conducted study

They were evaluated using the Dyadic Adjustment Scale, developed by Graham B. Spanier. The Dyadic Adjustment Scale (DAS) is regarded as the most used evaluation tool of marital adjustment. It is made up of 32 items that can be evaluated by one or both partners. For each item the subject must choose the answer closest to his/her opinion, from a list of items (fig. 1).

The DAS includes 4 subscales: (a) Dyadic consensus, (b) Dyadic satisfaction, (c) Dyadic satisfaction, (d) Emotional expresivity. It is used in contouring the quality of the dyadic relationship. It can be used for married couples as well as for couples living together or part of a short term relationship.

RESULTS AND DISCUSSION

This study was conducted on both sero-concordant and sero-discordant couples. Most couples enrolled in this study (50%) were sero-concordant (both partners were HIV-positive –15). 26% of couples were made-up an HIV-positive female and a non-infected male, and 24% were made-up of a non-infected female and an HIV-positive male (fig. 2).

The median age was 23 years, 33.4% of them came from rural areas. Average schooling level was 6 primary classes, with extremes between two classes of primary and higher education.

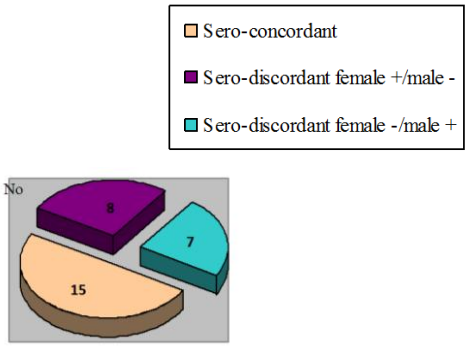

Fig. 2. The sero-concordance of the subjects

Only 50% of patients had a job, while the rest had no stable job and were not employed, 33.4% came from broken families or foster care.

100% of HIV infected patients are in active therapy, poliexperimented. Most patients have 5-6 treatment regimens (45%), with a maximum of 8-9 regimens.

Most of the couples enrolled (83.3%) were not married, as our study involved only 5 married couples. The relationship length varied between 4 moths and 15 years.

The Dyadic Adjustment Scale revealed high scores in couple's consensus and cohesion for both concordant and discordant couples.

In couples where both partners are HIV-positive, the DAS revealed average scores for all four areas of dyadic adjustment.

In couples where one partner is HIV-positive, and the other is not infected, low scores were seen in emotional expression and in the couple's satisfaction.

CONCLUSIONS

Engaging in a relationship is difficult for both healthy and infected individuals. Putting another's whishes and needs before your own is a challenge, especially in time

of illness.

The HIV-infected population in Romania is going through the same processes as their peers. The age of 22-24 is defined by self-development, self-affirmation and love. Regardless of their HIV status, young people naturally go through these stages.

The present study sheds a light on the difficulties faced by an HIV infected man or woman, part of a couple. It shows that communication and expressing one's emotions and concerns is a vital part of forming a steady and durable relationship. Consensus is important, as many decisions should be made by both partners. The couple's cohesion and satisfaction are closely linked and they depend on each individual's power to express their thoughts and feelings.

It is vital to have in mind that times change, and the small HIV-infected children from 1989 are now adolescents and young people with different needs that have to be sought to, both medically and psychologically.

ENDOCARDITA INFECTIOASA PLURIVALVULARA CU *ENTEROCOCCUS FAECALIS*

Simona Daniela Ionescu, Daniela Maria Tănase, Anca Ouatu, Paloma Manea
Universitatea de Medicină şi Farmacie „Grigore T. Popa" - Iaşi
Facultatea de Medicină
Disciplina de Medicină Internă - Medicală III - Cardiologie

PLURIVALVULAR WITH ENTEROCOCCUS FAECALIS INFECTIVE ENDOCARDITIS (Abstract): Infective endocarditis (IE) is a relatively rare disease that can take part of sepsis and may be a diagnostic and therapeutic challenge. Polyvalvular location of EI is rare. We present a patient of 60 years diagnosed with plurivalvular infective endocarditis by Enterococcus faecalis with septic complications, visceral, dragged, hospitalized for a psychiatric pathology, who raised the problems of diagnosis and treatment, without being able to make assessments on the entrance gate. For help in diagnosing this case proved that cardiac ultrasound studies recommended that a screening method for patients with bacteremia, but the presence of vegetation is the major criterion for diagnosis of EI. Blood cultures and echocardiography led to the diagnosis of infectious endocarditis. Also abdominal ultrasound confirmed the clinical suggestion of gravity, the septic multiviscerale release by splenic abscess image objectivity. Under vigorous antibiotic treatment and symptomatic treatment in combination evolution was to worse, death occurring after 15 days of hospitalization, toxic-septic shock being irreversible. Our case is particular by locating polyvalvular vegetation, the germ involved, the court altered the immunological and disseminator septic complications that have limited therapeutic options and made predictable fatal diagnosis. **Key words**: INFECTIVE ENDOCARDITIS, ENTERO-COCCUS FAECALIS

Cu toate progresele diagnostice şi terapeutice, EI continuă să rămână o provocare sub multiple aspecte, fiecare pacient constituind un motiv de reevaluare a cunoştinţelor în acest domeniu.

În decursul anilor s-a constatat că nici incidenţa, nici mortalitatea n-au scăzut, polimorfismul bolii pretând în continuare la erori de diagnostic, iar comportamentul social dezorganizat şi dezinformat sanitar menţine gradul de risc crescut ca incidenţă şi pronostic (1, 2).

Cazul prezentat ilustrează majoritatea problemelor discutate în diagnosticul şi tratamentul EI, în cadrul ghidurilor elaborate la nivel mondial, ghiduri ce se bazează pe opiniile experţilor rezultate din experienţa raportărilor unei patologii cu incidenţă scăzută, cu lipsa studiilor randomizate şi număr limitat de metaanalize (3,4).

Prezentăm cazul pacientului G.S. de 60 ani, sex masculin, ce a fost internat în Clinica a III-a Medicală Cardiologică, a Spitalului Clinic de Urgenţe „Sf. Spiridon" Iaşi, pentru febră, frison, dispnee, edeme gambiere, scădere ponderală (16 kg în aproximativ 6 luni), astenie marcată.

Boala a debutat insidios, cu 6-7 luni an-

terior, cu sindrom astenic, scădere ponderală progresivă şi episoade de edeme gambiere remise spontan; cu 4-5 săptămâni anterior adăugându-se febra moderată, un sindrom dispeptic frust, precum şi dispneea progresivă de efort, fiind trimis clinicii noastre pentru evaluare, investigaţii suplimentare şi tratament de specialitate.

Antecedentele eredo-colaterale nu au sugerat nici un element semnificativ, iar dintre antecedentele personale s-a remarcat doar o internare la Spitalul Clinic de Psihiatrie Nr. 7, Iaşi, cu 6 luni anterior, pentru o tulburare de personalitate anxioasă de tip impulsiv.

Starea generală la internare era gravă, cu adinamie, inapetenţă, caşexie. Examenul obiectiv a evidenţiat un pacient febril, cu febră de tip septic, palid, cu pliu cutanat persistent, hipocratism digital, mase musculare atrofice, polipneic (22 resp./min), tahicardic (FC=94 bătăi/min), cu un şoc apexian în spaţiul VII intercostal pe linia axilară anterioară, auscultator cardiac cu - suflu sistolic mitral şi tricuspidian, precum şi suflu diastolic aortic, TA=110/60 mmHg, edeme gambiere, hepatomegalie din spaţiul VI medioclavicular drept până la 6 cm sub rebord, cu reflux hepato-jugular şi splenomegalie de gradul I.

Explorările paraclinice iniţiale au relevat: anemie (Hb = 6,7 g%), leucocitoză uşoară (10.600 elem/mm^3) cu neutrofilie (77%), VSH: 107/120 mm, PCR pozitivă, hemocultură (1) pozitivă cu *Enterococcus faecalis*, uree = 66 mg%, creatinină = 2,47 mg%, Fe seric = 11µg%. Radiografia pulmonară a obiectivat mărirea diametrului transvers al cordului. Ecocardiografia transtoracică efectuată de la internare a decelat prezenţa cardiomiopatiei dilatative cu modificări de cinetică parietală segmentară şi prezenţa în mai multe incidenţe a unor formaţiuni vegetante flotante la nivelul valvelor mitrală (23/26 mm), aortică (13/11 mm), tricuspidiană (21/17 mm), cu regurgitări secundare severe şi elemente de hipertensiune pulmonară secundară severă (fig. 1, 2).

Fig. 1. Formaţiuni vegetante la nivelul VM,VT(A4C)

Fig. 2. Formaţiuni vegetante la nivelul VM, VA(A3C)

Un prim diagnostic de etapă a orientat spre o endocardită infecţioasă plurivalvulară cu *Enterococcus faecalis*, introducându-se tratament antibiotic în asociere cu Levofloxacină şi Amoxicilină + acid clavulanic (*Enterococcus faecalis* fiind sensibil conform antibiogramei) şi medicaţie simpto-

matică, formulă terapeutică sub care pacientul a continuat să facă febră, să prezinte dispnee, cu sindrom edematos persistent, tendință la degradare hemodinamică şi astenie marcată, motiv pentru care s-au continuat investigațiile.

Explorările paraclinice ulterioare au arătat progresia sindromului anemic (Hb= 5,9 g%), leucocitoză marcată (26.500/mm3), cu creşterea neutrofilelor, tombocitopenie (38.000/mm^3), VSH repetat cu valori mari (peste 100 mm/h), agravarea sindromului de retenție azotată (uree = 107 mg%, creatinină = 3,75 mg%), hepatocitoliză (TGO = 1376 UI/l, TGP = 676 UI/l), Quantiferon TB negativ, HIV negativ, hemoculturi (2) cu *Enterococcus faecalis* cu acelaşi profil de sensibilitate pe antibiogramă (izolat ca în prima hemocultură).

Ecografia abdominală a confirmat sugestia clinică a gravității, prin diseminări septice multiviscerale, prin obiectivarea imaginilor de abcedări splenice (Fig. 3,4).

Sub tratament susținut cu antibioterapie în asociere cu terapie simptomatică evoluția a continuat să se agraveze, decesul survenind după 15 zile de la internare, prin şoc toxico-septic ireversibil.

DISCUȚII

Incidența EI variază de la o țară la alta, fiind de aproximativ 3-10 cazuri/100.000 persoane pe an. Acest lucru poate reflecta mai degrabă diferențe metodologice între studii decât o variație adevărată (5, 6, 7, 8). De notat că în aceste studii incidența EI a fost foarte scăzută la pacienții tineri, dar creşte dramatic cu vârsta, incidența maximă fiind de 14,5 cazuri/100.000 persoane pe an la pacienții între 70 şi 80 de ani. În toate studiile epidemiologice asupra EI, raportul între incidența EI la sexul masculin față de sexul feminin este 2:1, raport sex ratio greu de explicat, în condițiile în care femeile au un prognostic mai prost şi suferă intervenții chirurgicale mai puțin frecvent decât bărbații (9).

EI pe cordul drept este estimată la 5-10% din cazurile de EI (5, 10, 11). Chiar dacă poate să apară la pacienți cu un stimulator cardiac permanent, defibrilator *cardioverter* implantabil, cateter venos central sau boli cardiace congenitale această situație este cel mai frecvent observată la pacienții cu abuz de droguri intravenoase. Incidența exactă a EI în abuzul de droguri intravenoase este necunoscută însă date recente arată o creştere a numărului spitalizărilor în EI asociată cu consumul de droguri

(12). Această boală apare mai frecvent la pacienții cu abuz de droguri intravenoase care sunt HIV pozitivi, în mod particular la cei cu imunodepresie avansată (11, 12, 14). Lezarea valvelor inimii drepte prin injectarea de materiale particulare asociată cu igiena defectuoasă la locul injectării, administrarea de soluții contaminate şi imunitatea scăzută sunt câteva din ipotezele fiziopatologice care stau la baza apariției EI pe cordul drept în abuzul de droguri intravenos (13). Deşi valva tricuspidă este locul uzual de infecție în abuzul de droguri intravenoase, infecția valvei pulmonare şi a valvulei lui Eustachio pot fi de asemenea observate, iar EI a inimii stângi nu este neobişnuită la acest grup de pacienți.

Cazul expus a prezentat o endocardită infecțioasă plurivalvulară cu *Enterococcus faecalis,* cu complicații septice viscerale, la un pacient tarat, spitalizat pentru o patologie psihiatrică, care a ridicat probleme de diagnostic şi tratament, fără a putea face aprecieri asupra porții de intrare. De un real ajutor în diagnosticul acestui caz s-a dovedit a fi ecografia cardiacă pe care studiile o recomandă ca metodă de screening pentru pacienții cu bacteriemie, dar care prin prezența vegetațiilor constituie criteriu major de diagnostic al EI.

Hemoculturile şi ecocardiografia reprezintă baza în diagnosticul endocarditei infecțioase. Ecocardiografia transtoracică trebuie realizată inițial, la prima suspiciune de sindrom infecțios cu afectare valvulară. EI dată de enterococ este produsă în 90% din cazuri de *Enterococul faecalis* şi mult mai rar de *Enterococul faecium* sau alte specii. Enterococii sunt înalt toleranți la antibioticele bactericide şi eradicarea lor necesită prelungirea terapiei (până la 6 săptamâni) cu combinații sinergice bactericide de inhibitori ai peretelui celular cu aminoglicozide, de asemeni pot fi rezistenți la multe antibiotice, inclusiv beta-lactamine (prin intermediul modificării PBP5 şi uneori prin producerea betalactamazelor), aminoglicozide şi vancomicină (15). Rezistența la vancomicină şi la beta-lactamine e observată în principal la *E. faecium.* Deoarece rezistența la ambele medicamente e rară, vancomicina se foloseşte în rezistența la beta-lactamine şi viceversa. Au fost obținute rezultate variabile cu linezolid, quinupristină, dalfopristină, daptomicină şi tigeciclină (16).

Mortalitatea intraspitalicească a pacienților cu endocardită infecțioasă variază de la 9,6 la 26%, dar diferă considerabil de la pacient la pacient. Identificarea pacienților cu risc crescut de deces poate schimba evoluția bolii şi îmbunătăți prognosticul, dar prezența complicațiilor septice diseminative este defavorabilă atât prin excluderea posibilității de corecție chirurgicală valvulară cât şi prin posibilitatea redusă de limitare a proceselor septice (17, 18, 20).

Chiar dacă embolii splenici sunt des întâlniți, ei rareori constituie un abces. Febra recurentă sau persistentă şi bacteriemia sugerează diagnosticul şi aceşti pacienți ar trebui evaluați prin tomografie computerizată sau IRM pe lângă ecografie. Tratamentul constă în antibioterapie adecvată. Splenectomia, indicată în cazurile de ruptură splenică sau abcese mari care răspund greu la terapia antibiotică, ar trebui făcută înainte de chirurgia valvulară, aceasta având prioritate în schimb în cazurile urgente. Drenajul percutanat este o alternativă la pacienții cu risc înalt chirurgical (19,21).

În literatură se citează influența asupra prognosticului în endocardita infecțioasă a 4 factori: caracteristicile pacientului, prezența sau absența complicațiilor cardiace sau non-cardiace, tipul de microorganism şi evaluarea ecocardiografică. Astfel se con-

sideră că persistența infecției și insuficiența renală sunt predictori ai mortalității la pacienții care necesită intervenție chirurgicală de urgență. Cum era și de așteptat, pacienții care au indicație de operație, dar care nu pot fi supuși acesteia din cauza riscului operator au cel mai rău prognostic (19).

Cazul prezentat reprezintă particularitate prin localizarea multivalvulară a vegetațiilor, prin germenele implicat, prin terenul alterat imunologic și prin complicațiile septice diseminative care au limitat posibilitățile terapeutice și a făcut predictibil diagnosticul infaust.

NOUTĂȚI

DESCIFRAREA UNUI CIRCUIT NEURONAL CARE MEDIAZĂ APETITUL

Neuronii hipotalamici care exprimă AgRP, neuropeptidul Y şi GABA stimulează apetitul şi creşterea în greutate, prin integrarea diferitelor semnale hormonale, nutriționale şi neuronale.Ablația experimentală a acestor neuroni la şoareci determină blocarea senzației de foame. Se apreciază că scăderea semnalelor GABA de către neuronii ce exprimă AgRP de la nivelul nucleului parabrahia (PBN) determină inhibarea apetitului.Neuronii glutamatergici şi neuronii serotoninergici caudali controlează excitabilitatea nucleului PBN şi inhibă senzația de foame. Inactivarea genetică a semnalelor glutamatergice de către receptori glutamici de tip N-metil D-aspartat la nivelul PBN previne înfometarea. În aceste condiții, PBN poate fi perceput drept sediul integrării semnalelor provenite din diverse regiuni cerebrale, pentru a asigura modularea bidirecțională a saţietății şi greutății corporale (Wu Q., Clark M.S., Palmiter R.D. Deciphering. A neuronal circuit that mediates appetite. *Nature* 2012; 594/97) .

EVALUAREA COMPARATIVĂ A SCORURILOR PROGNOSTICE ÎN EMBOLIA PULMONARĂ

Iulia-Cristina Roca[1], Viviana Aursulesei[2], M. Roca[1] , M.D. Datcu[2]
1. Doctorand al Universităţii de Medicină şi Farmacie "Grigore T. Popa" - Iaşi
Sp. Clinic Judeţean de Urgenţă ,,Sf. Spiridon" - Iaşi
2. Clinica I Medicală-Cardiologică ,,C.I. Negoiţă"

COMPARATIVE EVALUATION OF PULMONARY EMBOLISM PROGNOSTIC SCORES (Abstract): **Aim:** Pulmonary embolism is a life threatening disease and one of the main causes of in-hospital mortality.There are multiple risk stratification scoring systems for the forecast of the outcomes in patients with pulmonary embolism. **Material and methods:** We conducted a prospective observational cohort study to evaluate the comparative validity of four prognostic models: pulmonary embolism severity index (PESI), simplified PESI score, PESI risk classes and shock index, for predicting short-term mortality in acute pulmonary embolism. The PESI and PESI - simplified scores and shock-index were calculated. PESI scores were segregated into risk class (I-V) obtaining PESI classes. Shock index was dichotomized into 0 (for value <1) versus 1 (for value >1) risk groups. We determined the area under Receiver Operating Characteristic curve, the sensitivity, specificity, likelihood ratio (LR+, LR-) for PESI score, simplified PESI score, PESI risk classes and shock index, to compare the ability of these scoring tools. **Results:** The cohort consisted of 362 subjects. The mortality was 21.54%. The sensitivity, specificity and likelihood ratios were different between scores but the area under *Receiver Operating Characteristic* curve showed values in range 0,6-0,7. **Conclusions:** The assessed prognostic scores performed comparably for identifying pulmonary embolism patients at short-term risk of mortality, even for PESI score segregated in risk classes and dichotomized version of shock index. **Key words**: PULMONARY EMBOLISM, MORTALITY, PROGNOSTIC SCORE

Embolia pulmonară (EP) reprezintă un domeniu de patologie cu incidenţă ridicată (1 milion de persoane anual în Statele Unite ale Americii), marcat de morbiditate şi mortalitate crescută, respectiv 100000 de subiecţi anual şi de costuri ale tratamentului bolii de 1 bilion de dolari anual (1,2).

Având în vedere morbi-mortalitatea prin EP considerăm utilă o evaluare obiectivă complexă a scorurilor prognostice disponibile la acest moment privind riscul de deces precoce la aceşti subiecţi.

Scopul studiului nostru constă în evaluarea puterii diagnostice pentru predicţia riscului de mortalitate în spital, în EP, a următoarelor scoruri clinice: scorul PESI (Pulmonary Embolism Severity Index), clasele de risc PESI (Clasa_PESI), scorul PESI simplificat (PESI_S), respectiv indexului de şoc (Index_soc). Astfel am realizat evaluarea relaţiei dintre valorile scorurilor clinice (PESI, Clasa_PESI, PESI_S, Index_soc) şi mortalitate, la pacienţii cu EP; calcularea pragului de diagnostic, a puterii

diagnostice, a sensibilității, specificității, raportului de probabilitate negativ, respectiv pozitiv pentru fiecare dintre scorurile clinice evaluate; analiza comparativă a puterii diagnostice în predicția riscului de mortalitate în EP a celor patru scoruri clinice.

MATERIAL ŞI METODE

Am realizat un studiu de cohortă prospectiv, pe un lot de 362 pacienții asistați în Unitatea Primire Urgențe a Spitalului Clinic Județean de Urgență ,,Sf. Spiridon" şi internați, în perioada 2004-2010, în Clinica I Medicală Cardiologie ,,C.I.Negoiță" cu diagnosticul de embolie pulmonară.

Pentru pacienții incluşi în studiu s-a evaluat prognosticul pe termen scurt, respectiv, mortalitatea pe parcursul internării. Criteriile de includere în studiu au fost: pacienți cu vârsta între 16 şi 95 ani şi diagnosticul de embolie pulmonară (confirmat ecocardiografic, computer tomografic, scintigrafic sau necroptic). Criterii de excludere au avut în vedere prezența semnelor de sindrom posttrombotic la prima internare şi lipsa consimțământului informat.

Suplimentar față de protocolul de diagnostic al emboliei pulmonare, la fiecare pacient s-au aplicat patru scoruri prognostice pentru riscul de mortalitate, specifice acestei condiții patologice: scorul PESI, clasele de risc PESI, scorul PESI simplificat (tab. I, II) şi indexul de şoc.

TABELUL I

Scorurile PESI (3) şi PESI – simplificat (4)

	PESI original	PESI simplificat
Vârsta	Exprimată în ani	>80 ani = 1 punct
Sexul masculin	+10	
Cancer	+30	= 1 punct
Insuficiență cardiacă	+10	= 1 punct
Afecțiune respiratorie cronică	+10	= 1 punct
Puls > 110/ minut	+20	= 1 punct
Tensiunea arterială sistolică<100mmHg	+30	= 1 punct
Frecvență respiratorie > 30/minut	+60	
Status mental alterat	+20	
SaO2<90 mmHg	+20	
Temperatură<36 grade Celsius	+20	

TABELUL II

Clasele de risc PESI (5)

Interpretare	Clasa de risc EP - PESI
<65	Clasa I
66 - 85	Clasa II
86-105	Clasa III
106-125	Clasa IV
>125	Clasa V

Indexul de şoc reprezintă un scor definit prin raportul dintre frecvenţa cardiacă şi valoarea tensiunii arteriale sistolice (6). În studiul nostru am utilizat o reprezentare dihotomică a indexului de şoc: 0 pentru o valoare subunitară a raportului şi1 pentru o valoare supraunitară a acestuia.

Din punct de vedere a implicaţiilor etice, toţi pacienţii incluşi în studiu, au semnat consimţământul informat referitor la utilizarea datelor personale şi medicale, anexat foii de observaţie, la momentul internării.

Datele studiului au fost gestionate cu ajutorul unei baze de date de tip Microsoft EXCEL, iar prelucrarea statistică s-a realizat cu ajutorul programelor dedicate SPSS 16.0. şi MedCalc 12.1. Pragul de semnificaţie statistică a fost ales p=0,05.

Comparaţiile au fost realizate cu ajutorul testului neparametric Mann-Whitney, având în vedere că datele studiate nu au fost variabile de tip continuu şi nu au respectat principiul normalităţii distribuţiei, sau a testului Chi-pătrat (Exact Fisher) pentru variabilele de tip dihotomic.

S-a aplicat analiza tip receiver operating characteristic (ROC) pentru caracterizarea fiecărui scor clinic studiat, din punct de vedere al pragului de diagnostic, puterii diagnostice (aria de sub curba ROC), sensibilităţii, specificităţii, valorii predictive negative şi pozitive, cât şi pentru realizarea de comparaţii între scorurile clinice. În scopul realizării unei analize obiective a scorurilor clinice, având în vedere că structura grupului de studiu în cercetarea noastră nu a fost echivalentă din punct de vedere al prevalenţei EP cu populaţia generală, s-a preferat folosirea raportului de probabilitate pozitiv/negativ (Likelihood Ratio: LR+, LR-) utilizării valorilor predictive, prezentând avantajul de a nu fi dependent de prevalenţa bolii. LR este util în calcularea probabilităţii posttest, fiind data probabilitatea pretest a unui test diagnostic.

REZULTATE

Urmărirea prospectivă a celor 362 de pacienţi cu embolie pulmonară a demonstrat o mortalitate în spital de 21,5% (78 de pacienţi au decedat).

1. Evaluarea scorurilor de risc la subiecţii supravieţuitori comparativ cu decedaţii. Evaluarea diferenţelor între supravieţuitori şi decedaţi din punct de vedere al scorului PESI, claselor PESI şi scorului PESI simplificat a arătat valori semnificativ statistic mai ridicate la decedaţi faţă de supravieţuitori (Mann Whitney p<0,001). De asemenea, evaluarea diferenţelor între supravieţuitori şi decedaţi din punct de vedere al indexului de şoc, a arătat o frecvenţă semnificativ statistic mai ridicată a valorii 1 a scorului la decedaţi faţă de supravieţuitori (Fisher Exact Test, p<0,001).

2. Analiza ROC individuală a scorurilor de risc. Analiza ROC pentru scorul PESI a stabilit o valoare de 0,691 (p<0,0001) pentru aria de sub curba, reprezentând puterea diagnostică sau eficacitatea testului. Valoare de 120 a scorului PESI, a fost determinată ca fiind valoarea prag, semnificativă pentru discriminarea între absenţa, respectiv prezenţa riscului de mortalitate la pacienţii cu EP. La nivelul valorii prag s-au stabilit valori ale sensibilităţii testului de 43,59, ale specificităţii de 90,85, ale valorilor raportului de probabilitate LR+ de 4,76, respectiv LR- de 0,62.

Analiza ROC pentru clasele PESI a stabilit o valoare de 0,693 (p<0,0001) pentru aria de sub curbă, reprezentând puterea diagnostică sau eficacitatea testului. Valoare >4 a scorului, a fost determinată ca fiind valoarea prag, semnificativă pentru discriminarea între absenţa, respectiv pre-

zența riscului de mortalitate la pacienții cu EP. La nivelul valorii prag s-au stabilit valori ale sensibilității testului de 35.9, ale specificității de 92.96, ale valorilor raportului de probabilitate LR+ de 5.10, respectiv LR- de 0,69.

Analiza ROC pentru scorul PESI simplificat a stabilit o valoare de 0,623 (p=0,0003) pentru aria de sub curbă, reprezentând puterea diagnostică sau eficacitatea testului.Valoare > 0 a scorului PESI_S, a fost determinată ca fiind valoarea prag, semnificativă pentru discriminarea între absența respectiv prezența riscului de mortalitate la pacienții cu EP. La nivelul valorii prag s-au stabilit valori ale sensibilității testului de 92.31, ale specificității de 29.93, ale valorilor raportului de probabilitate LR+ de 1.32, respectiv LR- de 0,26.

Analiza ROC pentru Index_soc a stabilit o valoare de 0,690 (p<0,0001) pentru aria de sub curbă, reprezentând puterea diagnostică sau eficacitatea testului. Valoare > 0 a scorului, a fost determinată ca fiind valoarea prag, semnificativă pentru discriminarea între absența, respectiv prezența riscului de mortalitate la pacienții cu EP. La nivelul valorii prag s-au stabilit valori ale sensibilității testului de 43.59, ale specificității de 94.37, ale valorilor raportului de probabilitate LR+ de 7.74, respectiv LR- de 0,6.

3. Analiza ROC comparativă a scorurilor de risc. Pentru toate cele patru scoruri diagnostice evaluate, valoarea ariei de sub curba ROC se încadrează în intervalul 0,6 – 0,7, corespunzător unei eficiențe diagnostice relativ slabe (fig. 1).

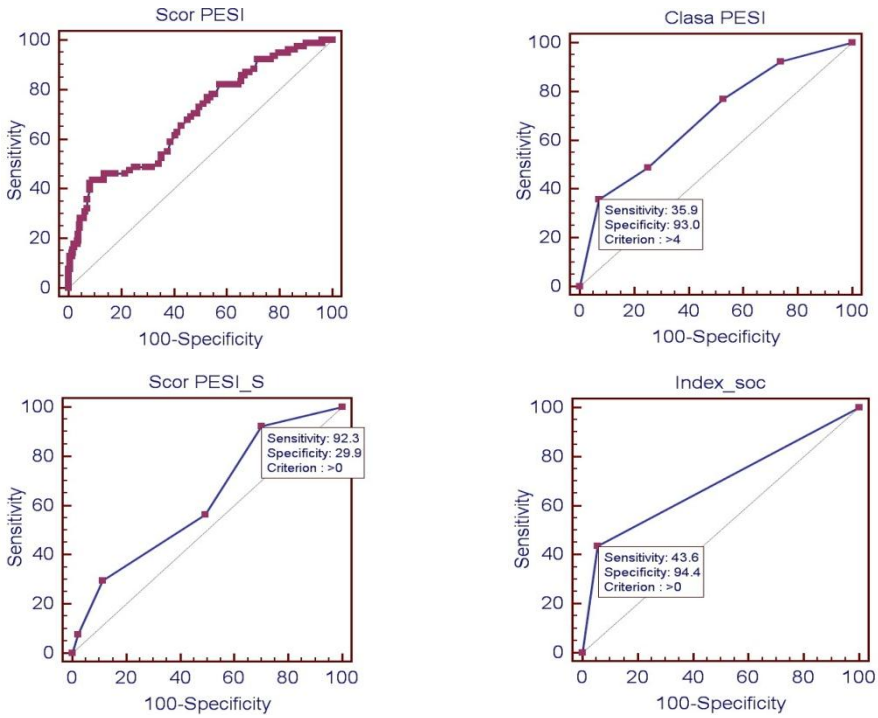

Fig. 1. Curba ROC pentru scorul PESI, clasele PESI, scorul PESI simplificat şi indexul de şoc, evaluări pentru lotul inclus în studiu.

Comparația eficacității celor patru scoruri de risc evidențiază următoarele elemente: eficacitatea scorului PESI nu este semnificativ diferită de eficacitatea claselor PESI şi a indexului de şoc, diferențele între ariile de sub curba ROC fiind nesemnificative statistic (p=0,783, respectiv p=0,978); eficacitatea claselor PESI nu este semnificativ diferită de eficacitatea indexului de şoc, diferența între ariile de sub curba ROC fiind nesemnificativă statistic (p=0,927); eficacitatea scorului PESI simplificat este semnificativ mai mică decât eficacitatea scorului PESI, claselor PESI şi a indexului de şoc, diferențele între ariile de sub curba ROC fiind semnificative statistic (p=0,0059, p=0,0051, p=0,0246); scorurile PESI, clasele PESI, şi indexul de şoc se remarcă prin valori reduse ale sensibilității (<50), dar prin valori mari, peste 90 ale specificității. Spre deosebire de acestea, scorul PESI simplificat are o valoare peste 90 a sensibilității, dar o specificitate foarte redusă, de aproximativ 30.

Din punct de vedere a raportului de probabilitate, indexul de şoc prezintă valoarea cea mai mare a LR+ (7.74) generând modificări moderate ale probabilității diagnosticului pozitiv. Clasele PESI şi scorul PESI prezintă valori mai mici ale LR+ (5.1, respectiv 4.76), generând modificări mici ale probabilității diagnosticului pozitiv.

PESI simplificat prezintă cea mai mică valoare a LR+ (1.32) fiind inferior celorlalte scoruri în generarea modificărilor de probabilitate pentru diagnosticul pozitiv.

Din punct de vedere al raportului de probabilitate negativ, pentru cele patru scoruri clinice, situația se prezintă astfel: scorul PESI simplificat prezintă cel mai bun raport de probabilitate LR-, fiind cel mai valoros dintre cele patru teste din punct de vedere al generarii modificărilor de probabilitate pentru diagnosticul negativ. Valoarea sa (0,26) se situează la limita dintre intervalul corespunzător generării modificărilor mici (0,5-1) şi cel corespunzător generării modificărilor moderate (0,5-0,2) ale probabilității diagnosticului negativ. Valorile LR- pentru PESI, clasele PESI şi indexul de şoc nu diferă semnificativ între ele (0,62, 0,69, respectiv 0,6), situându-se în zona caracteristică unui grad foarte mic de generare a modificărilor probabilităților diagnosticului negativ, fiind inferioare din acest punct de vedere scorului PESI simplificat.

DISCUȚII

Similar datelor din literatura de specialitate, studiul nostru arată o rată înaltă a mortalității intraspitaliceşti la pacienții diagnosticați cu embolie pulmonară, respectiv 21.54%. Mortalitatea după diagnosticul EP a fost raportată ca fiind de 25% (7). De asemenea, rezultatele studiului nostru sunt în concordanță cu rezultatele altor cercetări publicate referitoare la scorurile de evaluare a prognosticului în embolia pulmonară. Astfel, Chang şi colaboratorii demonstrează, similar rezultatelor noastre, că segregarea scorului PESI în clase de risc nu afectează semnificativ puterea prognostică a testului obținând o valoare a ariei de sub curba ROC de 0,684, apropiată de cea din studiul nostru (0,691) (8). Alte studii au obținut o putere diagnostică mai bună pentru scorul PESI. Astfel, în 2007, Jiménez evaluează comparativ scorul PESI şi scorul Geneva, obținând o valoare a ariei de sub curba ROC de 0,76 pentru PESI (9). În 2011 sunt publicate rezultatele unui studiu care evaluează comparativ indexul de şoc şi scorul PESI simplificat, arătând o eficiență mai bună a scorului PESI simplificat (10). Rezultatele noastre sunt diferite din acest punct de vedere, scorul PESI simplificat

dovedind eficiență diagnostică mai mică, comparativ cu celelalte trei scoruri dar, fiind cel mai bun din punct de vedere al raportului de probabilitate negativ (LR-).

În plus, folosind o variantă dihotomică a indexului de şoc, am obținut rezultate comparative cu celelate teste.

CONCLUZII

Din punct de vedere al eficacității diagnostice în evaluarea riscului de mortalitate, în studiul nostru, scorul PESI, clasele PESI, scorul PESI simplificat şi indexul de şoc se caracterizează prin valoari comparabile ale ariei de sub curba ROC în intervalul 0,6 – 0,7, corespunzătoare unei puteri diagnostice relativ slabe. Eficacitatea scorului PESI simplificat este semnificativ mai mică decât eficacitatea scorului PESI, claselor PESI şi a indexului de şoc.

Scorurile PESI, clasele PESI, şi indexul de şoc se remarcă prin valori reduse ale sensibilității (<50) dar prin valori mari, peste 90 ale specificității iar scorul PESI simplificat are o valoare peste 90 a sensibilității dar o specificitate foarte redusă, de aproximativ 30.

Indexul de şoc prezintă valoarea cea mai mare a LR+ (7.74) putând genera modificări moderate ale probabilității diagnosticului pozitiv, iar scorul PESI simplificat prezintă cel mai bun raport de probabilitate LR-, fiind cel mai valoros dintre cele patru teste din punct de vedere al generarii modificărilor de probabilitate pentru diagnosticul negativ.

THE EVALUATION OF HEPATOPROTECTIVE EFFECT OF SILYMARIN, *PHYLLANTHUS NIRURI* EXTRACT AND CHOLINE COMBINATION (Abstract): The high incidence of liver diseases due to the use of xenobiotics and unhealthy lifestyle is associated with increased need for hepatoprotective product administration. **Aim:** The hepatoprotective effect of the combination silymarin / *Phyllanthus niruri* extract / choline was investigated in comparison with silymarin alone in patients with hepatic steatosis, in an open clinical study. **Material and methods:** 101 patients with non-alcoholic hepatic steatosis confirmed by high values of serum transaminases and ultrasonography were included in the study. The patients were divided into two groups, group A received 150 mg silymarin three times daily, and group B a hepatoprotective complex (120 mg silymarin / 225 mg *Phyllanthus niruri* extract / 60 mg choline) three times daily, for 6 months. The hepatoprotective effects were assessed through the evolution of the following laboratory parameters: aspartate transaminase (AST), alanine transaminase (ALT), gamma-glutamyl transferase (GGT), alkaline phosphatase, serum bilirubin and serum cholesterol at 3 and 6 months after the initiation of the hepatoprotective treatment. **Results:** Both products were effective in the normalization of liver function, but the combination silymarin / *Phyllanthus niruri* extract / choline showed significantly better results than silymarin alone, considering the normalization of the hepatic parameter values after 3 and 6 months. The risk for hepatoprotective failure was significantly lower with the combination silymarin / *Phyllanthus niruri* extract / choline *versus* silymarin alone, the number needed to treat (NNT) being 3.7 after 3 months and 2.5 after 6 months. **Conclusions:** The combination silymarin / *Phyllanthus niruri* extract / choline induced a better liver protection than silymarin alone. **Keywords***: PHYLLANTHUS NIRURI*, SILYMARIN, CHOLINE, HEPATIC STEATOSIS, HEPATOPROTECTIVE.

Liver diseases register an increasing prevalence in Europe. The increased intake of alcohol, xenobiotics, junk-food combined with an unhealthy lifestyle and, finally, the infections caused by hepatitis viruses contribute to this *status quo* (1, 2). In Romania, non-alcoholic hepatic steatosis alone is diagnosed in 20% of the patients presenting for an internal medicine consultation, according to a survey published in 2008 (3, 4). The warnings about the complications associated with non-alcoholic steatosis (5) indicate the need for treatment of patients and the correction of risk factors

(6, 7).

The patients with liver diseases are advised to use a large variety of hepatoprotective products, apart from the specific antiviral treatment in case of viral hepatitis. Of the herbal products, those containing silymarin standardized extracts from *Cardui mariae fructus* have a privileged position among the hepatoprotective products. A recent systematic review with meta-analysis of randomized and controlled clinical trials evaluating the effect of silymarin on biochemical indicators in patients with liver disease have found a statistical significant effect of silymarin in decreasing aspartate transaminase (AST) and alanine transaminase (ALT), but not gamma-glutamyl transferase (GGT) (8). The decrease in hepatocyte oxidative stress and lipid metabolism regulation are considered the main effects of silymarin in steatosis (9).

The aim of this study was to investigate the hepatoprotective effect of the combination silymarin / *Phyllanthus niruri* extract / choline in comparison with silymarin alone, to assess the contribution of *Phyllanthus niruri* (an ayurvedic herb) extract and choline (an essential nutrient for the optimal liver functioning) to the hepatoprotective effect of silymarin.

MATERIALS AND METHODS

Study population. Patients aged 18 to 80 years old, diagnosed with non-alcoholic hepatic steatosis confirmed by high values of serum transaminases and ultrasonography, were enrolled in this clinical study at "Gen. Dr. Aviator Victor Anastasiu" National Institute of Aeronautical and Space Medicine, Bucharest, Romania. The inclusion criteria were: patients with abnormally elevated level of at least one of the enzyme AST, ALT or GGT, according to the method used by the laboratory of the medical unit. Abnormal were considered the levels of AST above 36 IU / L in women and 59 IU / L in men, ALT above 52 IU / UL in women and 72 IU / L in men and of GGT higher than 73 IU / L in both genders. The exclusion criteria were patients who followed antiviral therapy or candidates for specific antiviral therapy for hepatic viral infections.

The patients randomly received either silymarin 150 mg three times / day for 6 months (food supplement that contains 150 mg silymarin / tablet) (group A) or a combination of 120 mg silymarin / 225 mg *Phyllanthus niruri* extract / 60 mg choline three times daily (food supplement) (group B). All the patients were advised to eat a healthy diet and avoid alcoholic (ethanolic) beverages and highly processed foods. Physical exercise programs were indicated for the overweight and obese patients. The patients were assessed at baseline and after 3 and 6 months.

Evaluation criteria and outcome measures. At every time points, the patients were assessed for: AST, ALT, GGT, alkaline phosphatase, serum bilirubin, and serum cholesterol. In addition, blood sugar level and blood pressure were measured to investigate the impact of 225 mg of *Phyllanthus niruri* extract / dose on these parameters. Blood sugar and blood pressure were considered because non-clinical studies described for *Phyllanthus niruri* a decrease in blood sugar, comparable with that induced by glibenclamide (10, 11, 12) and blood pressure, comparable with the one induced by hydrochlorothiazide (13); but the experience from well-organized studies in human subjects is sparse. Side effects that could occur following the administration of both products have been monitored.

Statistical analysis.

The results were subjected to statistically interpretation using *EpiInfo* software; Z-test was used to determine the significance of the differences between the results in the two groups. The relative risks (RR) of not obtaining the normalization of laboratory parameters with silymarin / *Phyllanthus niruri* extract / choline *versus* silymarin administration and the NNT value were calculated.

RESULTS

The clinical study was conducted between March 2015 and December 2015. One hundred and one patients met the inclusion criteria and have completed the 6-month hepatoprotective treatment. The patients were randomly divided into 2 groups: 50 patients (28 M / 22 F) in group A (silymarin group) and 51 patients (35 M / 16 F) in group B (silymarin / *Phyllanthus niruri* extract / choline). The initial characteristics of the groups (demographic data and laboratory parameters) are summarized in first table. Initially, the groups were generally homogenous. Significant statistical differences were recorded only for ALT, which was significantly higher in the group B ($p<0.001$) and patient age which was significantly greater in group A ($p=0.04$).

TABLE I

Demographic data and laboratory parameters at baseline

Parameters	Group A (n= 50)	Group B (n= 51)	*p* value
Demographic data			
Sex, Male / Female (%Male / %Female)	28 / 22 (56 / 44)	35 / 16 (68.63.31.37)	0.19
Age, years mean ± SD (range)	58.72 ± 10.46 (37 - 81)	53.71 ± 12.45 (25 - 77)	0.04
Body weight, Kg mean ± SD (range)	84.11 ± 11.94 (58 - 114)	82.29 ±1 2.74 (68 - 118)	0.39
Para-clinical parameters			
AST, IU / L mean ± SD (range)	68.76 ± 30.26 (30 - 208)	68.94 ± 29.93 (39 - 180)	0.98
ALT, IU / L mean ± SD(range)	99.52 ± 26.72 (64 - 173)	126.92 ± 47.62 (68 - 280)	<0.001
GGT, IU / L mean ± SD (range)	73.72 ± 30.03 (28 - 152)	72.75 ± 34.09 (30 - 180)	0.88
Alkaline Phosphatase, U / L mean ± SD (range)	70.94 ± 23.33 (37 - 165)	67.20 ± 22.20 (37 - 145)	0.41
Serum Bilirubin, mg / dL mean ± SD (range)	1.11± 0.28 (0.8 - 2.2)	1.06 ± 0.18 (0.7 - 1.5)	0.35
Serum cholesterol, mg / dL mean ± SD (range)	223.54 ± 33.40 (164 - 295)	230.39 ± 31.20 (175 - 311)	0.29
Systolic Blood Pressure, mm Hg mean ± SD (range)	134.72 ± 13.22 (110 - 170)	130.92 ± 9.72 (112 - 148)	0.10
Diastolic Blood Pressure, mm Hg mean ± SD (range)	82.08 ± 9.37 (60 - 105)	81.75 ± 9.37 (60 - 100)	0.86
Blood Glucose, mg / dL mean ± SD (range)	108.62 ± 21.14 (82 - 197)	103.71 ± 15.74 (65 - 142)	0.19

n – number of patients, SD – standard deviation

Comparing to the baseline, at 3 months, significantly lower levels were recorded in group B than in group A for serum ALT, AST, bilirubin, alkaline phosphatase and cholesterol. Only for GGT was found no significant decrease in group B *versus* group A.

At 6 months, all the monitored parameters of the liver function were significantly lower in group B *versus* group A (fig. 1-6, tab. II).

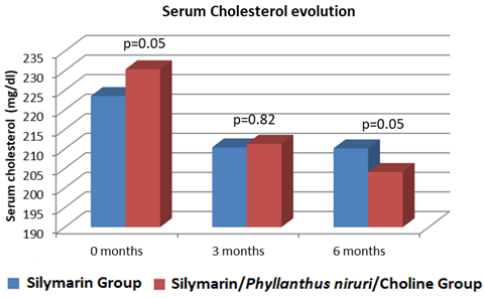

Fig. 6. Mean alkaline phosphatase levels at baseline, after 3 and 6 months

TABLE II

The evaluation of laboratory parameters after 3 and 6 months of hepatoprotective product administration

Laboratory parameter	3 months			6 months		
	Group A (n=50) mean ± SD (range)	Group B (n=51) mean ± SD (range)	*p*-value	Group A (n=50) mean ± SD (range)	Group B (n=51) mean ± SD (range)	*p*-value
AST, UI / L	54.02 ± 14.8 (30 - 112)	48.74 ± 9.82 (30 - 75)	0.04	48.56 ± 8.34 (34 - 70)	41.63 ± 9.05 (23 - 69)	<0.0001
ALT, UI / L	69.7 ± 16.57 (32 - 110)	67.36 ± 12.80 (43 - 108)	0.43	65.68 ± 9.84 (47 - 88)	56.43 ± 11.18 (37 - 93)	<0.0001
GGT, UI / L	60.12 ± 17.04 (25 -9 2)	57.76 ± 16.80 (21 - 98)	0.49	57.26 ± 14.94 (28 - 83)	51.58 ± 13.99 (27 - 80)	0.05
Alkaline phosphatase, U / L	64.38 ± 18.46 (29 - 98)	57.55 ± 16.28 (30 - 102)	0.05	64.98± 12.39 (40-88)	58.48± 14.52 (23-98)	0.02
Serum bilirubin, mg / dL	1.11 ± 0.25 (0.8 - 2.1)	1.01 ± 0.13 (0.8 - 1.4)	0.01	1.17 ± 0.30 (0.9 - 2.1)	1.01 ± 0.12 (0.8 - 1.3)	0.02
Serum cholesterol, mg / dL	210.41 ± 20.10 (172 - 241)	211.33 ± 16.87 (185 - 258)	0.82	210.14 ± 13.94 (169 - 230)	204.11 ± 11.39 (180 - 230)	0.05
Systolic Blood Pressure, mg Hg	129.36± 7.95 (115-145)	128.06± 6.51 (115 - 140)	0.37	128.54 ± 7.80 (110 - 140)	126.92± 7.99 (110 - 145)	0.30
Diastolic Blood Pressure, mg Hg	80.20± 5.80 (70-90)	80.06 ± 6.53 (60 - 95)	0.91	80.44 ± 6.95 (60 - 90)	78.92± 5.60 (65 - 90)	0.23
Blood sugar, mg / dL	104.12 ± 11.71 (82 - 139)	100.88 ± 10.07 (80 - 131)	0.14	102.6 ± 9.48 (85 - 127)	101.59 ± 6.11 (90 - 118)	0.52

n – number of patients, SD – standard deviation

The results are more relevant when considering the rate of hepatic enzyme normalization. At baseline, in both groups, all patients had abnormal level of at least one of the ASL, ALT or GGT enzymes, but after 3 months 10 (20%) patients in group A and 24 (47.1%) patients in group B had normal hepatic enzyme levels. Thirteen (26%) patients in group A and 34 (66.7%) patients in group B had normal hepatic enzyme levels after 6 months (fig. 7, tab. III).

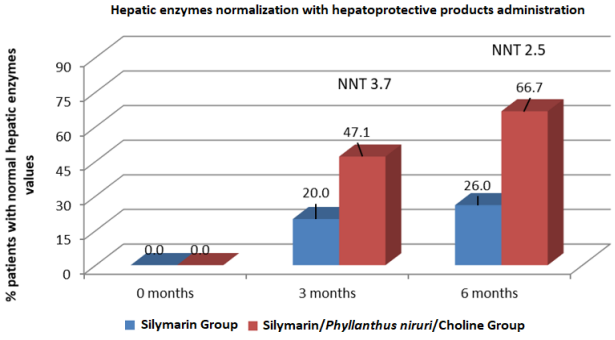

Fig. 7. The rate of hepatic enzyme normalization after 3 and 6 months of treatment with hepatoprotective products

TABLE III

Comparison of the risk for hepatoprotective treatment failure between the two treatment groups - intention-to-treat approach

	Group A (n=50)	Group B (n=51)	*p* - value	RR (95% CI)	NNT
Patients uncured after 3 months n, (%)	40 (80%)	27 (53.9%)	0.0058	0.66 (0.49 to 0.89)	3.696
Patients uncured after 6 months n, (%)	37 (74%)	17 (33.3%)	0.0002	0.45 (0.30 to 0.69)	2.459

RR – risk ratio, NNT – number needed to treat

No statistically significant differences in blood sugar level and blood pressure were recorded between the two groups (tab. II) and no side effects were reported in both groups.

DISCUSSION

Silymarin standardized dry extracts from *Cardui mariae fructus* are used in Europe at least since 1974 in liver diseases such as toxic liver damage, chronic inflammatory liver disease, cirrhosis and are also clinically proven to be effective in non-alcoholic steatosis (14, 15). Silibinin, the main component of flavonolignan complex silymarin, stimulates the protein biosynthesis and induces stabilization of the hepatocyte membranes, exerts antifibrotic effect and prevents the cellular damage and the secretory failure associated with various hepatotoxins (15).

Phyllanthus niruri is an ayurvedic herb, traditionally used for the effect on kidney stones and hepatoprotective effect. Aerial parts are rich in lignanic compounds such as: phyllanthin and hypophyllantin responsible for hepatic tissue regenerating effects (16). *Phyllanthus niruri* has an efficient antitoxic effect, confirmed by acetaminophen, carbon tetrachloride, and thioacetamide-experimentally induced hepatotoxicity models (16, 17, 18, 19). Similar hepatoprotective activities both for silymarin and *Phyllanthus niruri* have been recorded in paracetamol-induced liver toxicity (20). The hepatoprotective effect of *Phyllanthus niruri* was clinically demonstrated and explained by the increase in physiological antioxidants, reduced lipid peroxidation in hepatocyte membrane and counteracting of the destructive effects of free oxygen radicals in the liver (21). The combination between silymarin and *Phyllanthus niruri* demonstrated synergistic hepatoprotective effect in a non-clinical study in rats with carbon tetrachloride-induced hepatotoxicity. A superior effect in normalizing the blood biochemical parameters was recorded for the combination of silymarin with *Phyllanthus* in comparison with silymarin or *Phyllanthus* alone (22). Another non-clinical research (23) supported the beneficial effects of the combination of silymarin and *Phyllanthus*; more efficient hepatoprotective effects were recorded for this combination compared with silymarin alone. The study considered the prevention of liver injury and the normalization of transaminase values in carbon tetrachloride - and paracetamol-induced hepatotoxicity models.

Choline is a source of methyl for the hepatic transmethylation reactions and it is also an essential component of cell membranes and plasma lipoproteins. Choline deficiency is associated with liver injuries (hepatic steatosis and high level of alanine

aminotransferase) that have been recorded both in choline-free parenterally fed patients (24) and in the choline-poor diet in post-menopausal women (25); these effects are reverted by choline dietary supplementation. Currently, choline is the single nutrient with specific liver health claim approved by the *European Food Safety Authority* "maintenance of normal liver function" (26).

The current study investigated the hepatoprotective effect of the combination silymarin / *Phyllanthus niruri* extract / choline in comparison with silymarin alone.

The study confirmed the hepatoprotective effect assessed by the normalizing effect on serum transaminases for silymarin alone and the combination silymarin / *Phyllanthus niruri* extract / choline. However, the combination silymarin / *Phyllanthus niruri* / choline was significantly more efficient than silymarin alone in normalizing the AST, ALT and GGT levels after 3 and 6 months of administration. A brief assessment revealed that the results obtained after 6 months with silymarin alone have been already obtained after 3 months with the combination silymarin / *Phyllanthus niruri* extract / choline, even though a lower dose of silymarin was used in the combination product. Results with statistical significance favorable for silymarin / *Phyllanthus niruri* / choline combination were also obtained for alkaline phosphatase, serum cholesterol and serum bilirubin.

The study also aimed to investigate if *Phyllanthus niruri* extract influences the glycemic profile and blood pressure. In both groups, a slight decrease of blood sugar and blood pressure was recorded. No statistically significant difference between groups in the levels of these parameters was recorded. On the other side, most patients had quite normal levels of these parameters at the inclusion in study: higher rate of abnormal levels at inclusion was observed for the blood sugar levels. Twenty-one (42%) patients in group A and 16 (31.4%) patients in group B presented blood sugar levels above normal ranges at baseline. After 6 months of hepatoprotective treatment, 12 (24%) patients in group A and 6 (11.8%) patients in group B presented higher blood sugar levels. No significant difference in blood sugar levels was found between groups ($p=0.52$) and no influence of *Phyllanthus niruri* on blood sugar levels could be demonstrated. The results are not in agreement with the results of non-clinical studies that demonstrated the hypoglycemiant effect (10, 11, 12) and the hypotensive effect mediated by the diuretic effect of *Phyllanthus niruri* (13, 27). In our study, no statistically significant differences were recorded between group B, receiving silymarin / *Phyllanthus niruri* extract / choline combination and group A, receiving silymarin alone.

No side effects were reported, and this study confirmed the safety use of the combination silymarin / *Phyllanthus niruri* / choline.

CONCLUSIONS

The results of our clinical study indicate that the combination silymarin / *Phyllanthus niruri* extract / choline achieved a better liver protection than silymarin alone in patients with hepatic steatosis. Significantly better results were also obtained after 6 months of administration.

The combination silymarin / *Phyllanthus niruri* / choline showed a safety profile like silymarin alone since no adverse reactions were recorded.

PLACENTA ACCRETA FOLLOWING HYSTEROSCOPIC LYSIS OF ADHESIONS CAUSED BY ASHERMAN'S SYNDROME: A CASE REPORT AND LITERATURE REVIEW

Asherman's syndrome is defined as partial or complete obstruction of the uterine cavity primarily caused by intrauterine procedures and infections. Hysteroscopic adhesiolysis is commonly used to treat Asherman's syndrome. Although the frequency of placenta accreta is known to increase with pregnancy after hysteroscopic adhesiolysis, precise data remain unknown. We report a case of placenta accreta following hysteroscopic lysis of adhesions caused by Asherman's syndrome and IVF treatment and review the literature on placenta accreta following hysteroscopic adhesiolysis. It is necessary to consider placenta accreta as a complication of pregnancies after hysteroscopic adhesiolysis for Asherman's syndrome, particularly in those conceived using IVF. The incidence of placenta accreta is significantly higher in IVF pregnancies than in spontaneous pregnancies [16]. Esh-Broder et al. reported that the rate of placenta accreta in spontaneous pregnancies was 12 / 752 (1.2 / 1000), while that in IVF pregnancies was 30 / 24,441 (16 / 1,000). The higher rate of placenta accreta in IVF pregnancies may be due to the change in endometrial environment and morphological and structural changes to the endometrium due to the IVF treatment protocol (stimulation protocol). Intrauterine adhesions (IUA) severity is associated with greater reduction in fertility thereby increasing the likelihood that affected patients will need to undergo IVF to have a successful pregnancy. The extent of endometrial loss increases with IUA severity, which likely confers a greater risk of placenta accreta. For this reason, doctors should be aware that IVF pregnancy following hysteroscopic adhesiolysis involves a greater risk of placenta accreta (Yuko Sonan, Shigeru Aoki, Kimiko Enomoto, Kazuo Seki, Etsuko Miyagi. Placenta Accreta following Hysteroscopic Lysis of Adhesions Caused by Asherman's Syndrome: A Case Report and Literature Review. *Case Reports in Obstetrics and Gynecology*, 2018, https://doi.org /10.1155/2018/6968382).

THE METABOLIC SYNDROME'S PREVALENCE IN A POPULATION OF TRANSPORT WORKERS (Abstract): The metabolic syndrome is a problem which regards public health this phenomenon being explined by the world –wide obesity epidemy.The metabolic syndromes prevalence varies with the studied populations.The unhealthy lifestyle which is defined by peoples sedentary character and unhealthy diets is being significantlly asociated with the metabolic syndromes prevalence growth. **Material and methods:** The study was performed on 836 individuals with ages between 25 and 65 years, who have a questionnare based interview.Their blood pressure was measured, some anthropometric measures were taken and several laboratory test were made. The diagnosis of metabolic syndrome was established according to the consensual deffinition that was published in October 2009. **Results and conclusions:** The metabolic syndrome is a compilation of clinical and biological elements which cause the individ to have a higher cardiovascular risk. The metabolic syndrome increased prevalance in the study is significantlly asociated with the growth of the obesitys and hypertensions prevalance**.** The lifestyle of the individuals from the study is based on unhealthy diets and sedentarism. **Key words:** METABOLIC SYNDROME, HYPERTENSION, OBESITY, SEDENTARISM, PREVALENCE

Sindromul metabolic (SM) este o constelaţie de factori clinico-biologici care conferă indivizilor un risc cardiovascular crescut (1).

Studiile populaţionale au arătat că SM dublează riscul evenimentelor cardiovasculare (2), iar la pacienţii nondiabetici creşte de 5 ori riscul de diabet zaharat tip 2 (3).

Hipertensiunea arterială este cea mai frecventă componentă individuală a SM fiind prezentă la 50-76% dintre cazuri.

De-a lungul timpului s-au acumulat multe cunoştinţe despre incidenţă, prevalenţă şi s-au adus unele informaţii nu numai cu privire la etiopatogenia SM, la originea sa multifactorială, ci şi în legătură cu factorii agravanţi ca: sedentarismul, disfuncţia endotelială etc (4, 5, 6, 7).

MATERIAL ŞI METODE

Studiul a fost realizat pe un lot de 836 subiecţi, lucrători în transporturi, care au răspuns la un interviu pe bază de chestionar, s-a determinat tensiunea arterială şi s-au efectuat măsurători antropometrice. Pentru subiecţii cu TA≥140/90 mmHg şi /sau

PT>94 cm s-a extins protocolul de studiu cu teste de laborator care au inclus glicemia à jeun, HDL-colesterolul, trigliceridele.

REZULTATE ŞI DISCUŢII

1. Repartiția pe grupuri de vârstă

Cel mai tânăr participant a avut vârsta de 25 de ani iar cel mai vârstnic 65 ani, media de vârstă pentru lotul de studiu fiind de 42,93 ani.

Cei mai mulți pacienți (35,4%) s-au încadrat în categoria de vârsta 35-44 de ani, cei mai puțin reprezentați au fost între 54-65 de ani (15,79%), celelalte categorii având o pondere de 26,32%(45-54 de ani) şi 22,4% (25-34 de ani).

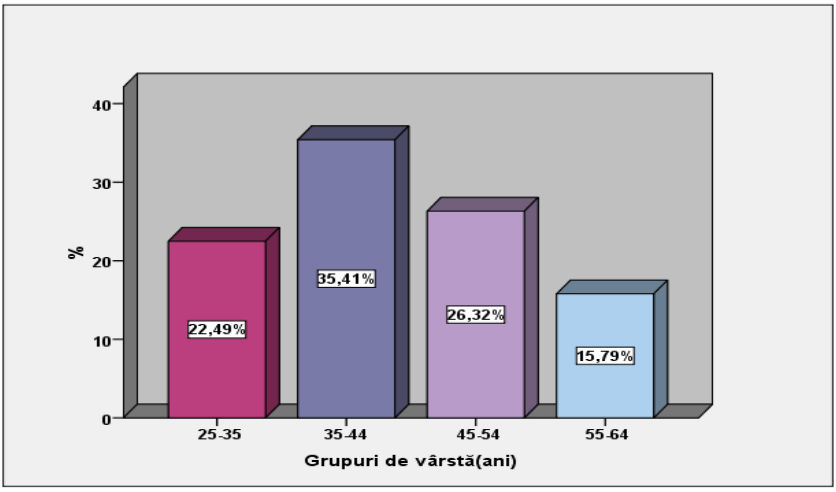

Fig. 1. Repartiția pe grupuri de vârstă

2. Prevalența sindromului metabolic

La nivelul întregului lot SM a fost prezent la 28,23% din subiecți şi la 64,47% din hipertensivi (fig. 2). S-a constatat că prevalența SM la lotul studiat este mai mare decât în populația generală, iar valorile prevalenței SM cresc cu vârsta fapt corelat parțial cu creşterea prevalenței HTA şi a anomaliilor glicemice (tab. I).

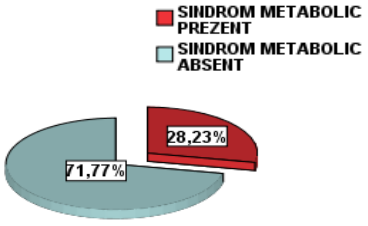

Fig. 2. Prevalența sindromului metabolic în lotul de studiu

TABELUL I

Prevalența SM pe grupuri de vârstă

Sindromul metabolic	Total cazuri	grupuri de vârstă(ani)							
		25-34		35-44		45-54		55-64	
Prezent	236	Nr.	%	Nr.	%	Nr.	%	Nr.	%
		28	11,9	72	30,5	76	32,2	60	25,4
Absent	600	160	26,7	224	37,3	144	24,0	72	12,0
Total	836	188	22,5	296	35,4	220	26,3	132	15,8

3. Prevalența obezității

Pentru cuantificarea obezității am utilizat măsurarea perimetrului taliei (PT) care conform definiției trebuie să fie mai mare de 94 cm. În ansamblul studiului procentul obezilor este semnificativ crescut 60,77% fapt explicabil prin caracteristicile lotului (sedentarism şi diete necorespunzătoare). Pentru o prezentare cât mai detaliată am încadrat subiecții în trei categorii funcție de PT (PT≤94 cm; PT 95-101 cm; PT≥102 cm).

S-a constatat că pacienții cu PT ≥102 cm (35,89%) au fost în număr aproape egal cu cel al pacienților fără obezitate (39,23%), dar în structura lotului s-au înregistrat 24,88% cu PT între 95-101 cm (fig. 3).

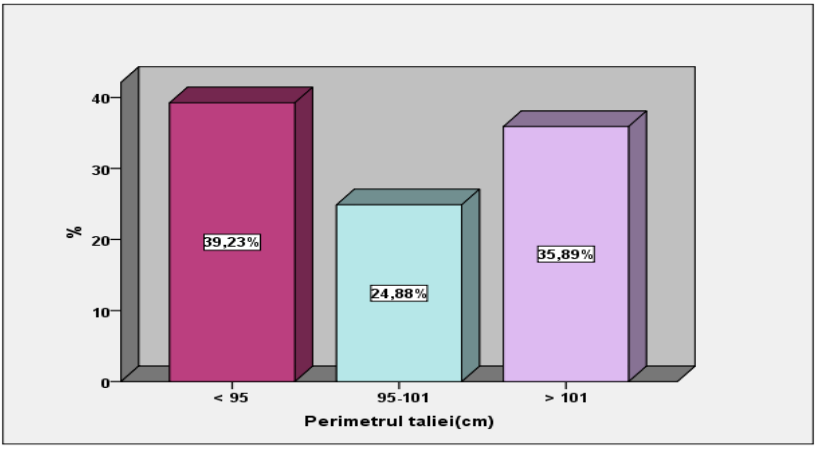

Fig. 3. Repartiția perimetrului taliei

4. Prevalența hipertensiunii arteriale

Din cei 836 pacienți care au răspuns la ancheta clinico-epidemiologică hipertensiunea arterială a fost prezentă la 36,4%. Luând în considerație faptul că lotul studiat a avut vârsta sub 65 de ani putem remarca o prevalență crescută a HTA comparativ cu datele din literatură, unde HTA se înregistrează la aproximativ 40% din populația adultă (fig. 4).

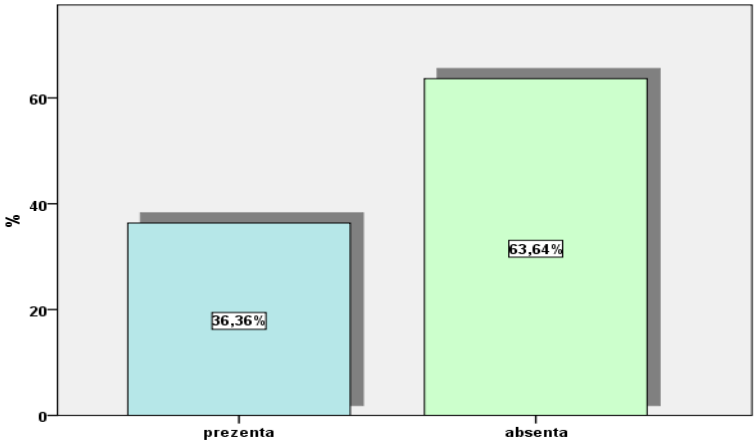

Fig. 4. Prevalența HTA în lotul de pacienți incluşi în studiu

CONCLUZII

Identificarea sindromului metabolic are valoare în contextul depistării factorilor de risc cardiovascular, talia hipertensivă fiind elementul de orientare.

Există limite în depistarea elementelor sindromului metabolic

Cooperarea interdisciplinară între rețeaua primară, şi cea de specialitate este obligatorie iar medicul de familie – are un rol important în supravegherea pacienților purtători ai factorilor de risc, coordonarea screening-ului pentru complicații şi educarea pacienților.

Sindromul metabolic este o constelație de factori clinico-biologici care conferă indivizilor un risc cardiovascular crescut.

Prevalența sindromului variază în funcție de populațiile studiate.

S-a dovedit că prevalența SM are valori crescute la lucrătorii în transporturi comparativ cu populația generală.

Hipertensiunea arterială se înregistrează, la peste 50 % dintre pacienții cu obezitate.

Cercetările au dovedit existența unei relații directe între stilul de viață nesanogen şi valorile ridicate ale prevalenței obezității, HTA şi SM.

CROSS - SECTIONAL STUDY TO EVALUATE RISK FACTORS IN INFANTS' MALNUTRITION (Abstract): Malnutrition is a major health problem in our country by maintaining a high number of infants with poor nutritional status. Various studies have highlighted the role of infant's malnutrition in the development of adult diseases. Methods: We made a cross-sectional study during six months (October 2010 - March 2011) on a group of 63 infants admitted in Pediatric Recovery Department-Children's Hospital, Iasi; we evaluated the presence of risk factors for malnutrition. The data were processed using SPSS 16 and EpiInfo 3.5.2. (December 2010). Results: The infants were predominantly female (52,4%); the most affected age group was 5-24 weeks (84,11%). Most of them came from rural areas (79,4%), from families with low socioeconomic income (95,2%), mothers with a low educational status (63,4%), housewives (88,9%). We noted the presence of previous diseases in 71,4% infants. Only 12 infants received breast milk for a short time (three weeks), the other 51 infants have been bottle-fed since birth. Complementary food was incorrect in 68,42% cases. With a proper diet the mean weight gain was 895,68 g and the Z score values (weight for age, height for age, weight for height) have improved during an average of 34,15 days; positive correlation between these factors is strong. Conclusions: Low socio-economic income, rural areas, low maternal educational level, diet errors, small infants with multiple previous diseases are the main risk factors in malnutrition's occurrence. We consider particularly important to solve social problems too, not only the medical, because when the infant returns in the same disadvantaged family there is an increased risk for malnutrition to recur. **Keywords**: MALNUTRITION, RISK FACTORS, Z SCORE, INFANT NUTRITION.

Malnutriţia reprezintă un indicator important în aprecierea stării de sănătate a populaţiei având în vedere corelaţiile care s-au stabilit între diverse afecţiuni ale adultului şi nutriţia inadecvată din perioada de sugar (1).

În plus, datele din literatură subliniază prezenţa unor efecte negative pe termen lung şi prin afectarea dezvoltării cerebrale. Astfel aproximativ 50% dintre copiii afectaţi de malnutriţie în primul an de viaţă vor prezenta afectarea comportamentului verbal şi socio-afectiv în perioada de adult (2,3).

Studiile desfăşurate până în prezent au evidenţiat că mortalitatea infantilă este determinată în peste 50% din cazuri de mal-

nutriţie (4,5), iar estimările efectuate subliniază posibilitatea reducerii acesteia cu cel puţin o treime dacă malnutriţia ar fi eliminată (4,6).

MATERIAL ŞI METODĂ

Am efectuat un studiu retrospectiv, pe o perioadă de 6 luni (octombrie 2010 – martie 2011), pe un lot de 63 sugari, a căror vârstă la internare a fost cuprinsă între 5 şi 48 de săptămâni, internaţi în Secţia Recuperare Pediatrică a Spitalului Clinic de Urgenţă pentru Copii „Sfânta Maria" Iaşi, la care am evaluat prezenţa unor factori de risc în apariţia malnutriţiei.

Criteriul de includere în studiu a fost prezenţa malnutriţiei protein-energetice (Protein Energy Malnutrition – PEM) apreciată prin determinarea indicatorilor antropometrici recomandaţi de OMS (greutatea pentru talie, talia pentru vârstă, greutatea pentru vârstă) (7,8).

Pentru respectarea normelor deontologice ale cercetării, includerea copiilor în lotul de studiu a fost realizată după obţinerea, în prealabil, a consimţământului informat al aparţinătorilor legali ai acestora. Am redactat astfel, într-un limbaj accesibil, un formular de consimţământ informat care conţine date despre scopul, metodologia şi riscul redus al studiului (prelevarea probelor este non-invazivă şi nu provoacă discomfort), precum şi beneficiile ce rezultă prin participarea la acesta, garantând confidenţialitatea rezultatelor obţinute (9).

De asemenea, din foile de observaţie au fost preluate toate informaţiile referitoare la factorii ce pot favoriza apariţia malnutriţiei: mediul de provenienţă, nivelul socio – economic al familiei, date referitoare la mamă (stare civilă, nivel educaţional, ocupaţie, antecedente obstetricale), date referitoare la alimentaţia administrată anterior internării (tipul, durata şi modul de administrare al alimentaţiei, utilizarea unei alimentaţii corecte/incorecte), date despre antecedentele personale patologice.

Pentru evaluarea statusului nutriţional, atât la internare cât şi la externare, s-au determinat greutatea şi talia. Valorile greutăţii şi taliei pentru vârstă, precum şi ale greutăţii pentru talie au fost calculate, la internare şi la externare, cu ajutorul tabelelor de referinţă recomandate de Centers for Diseases Control (CDC)/National Center for Health Statistics (10).

Ulterior acestea au fost interpretate cu ajutorul scorului Z, ce exprimă valoarea antropometrică în număr de deviaţii standard inferioare sau superioare valorii mediane de referinţă (7).

La subiecţii incluşi în studiu, pe toată durata internării, au fost recomandate regimuri dietetice adaptate gradului de severitate a malnutriţiei. De asemenea au fost monitorizate evoluţia clinică şi sporul ponderal.

Toate datele de anamneză, cele antropometrice, de laborator precum şi valorile calculate ale scorului Z au fost introduse într-o bază de date în Excel. Aceasta a fost importată şi prelucrată cu ajutorul programului *SPSS 16.0* şi *EpiInfo 3.5.2*. (17 Decembrie 2010).

REZULTATE

Analizarea distribuţiei sugarilor ce au alcătuit lotul de studiu pe grupe de vârstă (5-12 săptămâni, 13-24 săptămâni, 25-36 săptămâni, 37-48 săptămâni) a evidenţiat prezenţa PEM în special la cei cu vârsta între 5 – 24 săptămâni (53 sugari - 84,11%) (fig. 1). Diferenţa între această grupă de vârstă şi grupele de vârstă 25 - 36, respectiv 37 – 48 săptămâni este semnificativă statistic ($p < 0,01 \text{ X } 10^{-5}$), la fiecare dintre acestea înregistrându-se numai câte 5 sugari (7,93%).

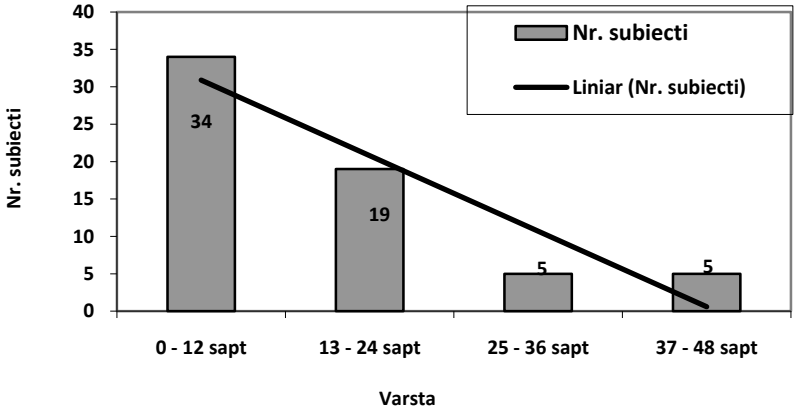

Fig. 1. Distribuţia subiecţilor incluşi în studiu pe grupe de vârstă

Au predominat sugarii de sex feminin (52,4% versus 47,6% sex masculin) însă diferenţa nu a fost semnificativă statistic (p = 0,50).

Majoritatea sugarilor cu PEM luaţi în studiu au provenit din mediul rural (50 sugari – 79,4%) (fig. 2), aproximativ jumătate dintre ei fiind din familii organizate (32 sugari – 50,8%, p = 0,007 X 10^{-2}), cu 1 – 2 copii (31 sugari – 49,20%, p = 0,09 X 10^{-5}**)** şi cu un nivel socio – economic scăzut în majoritatea cazurilor (60 sugari – 95,2%, p = 0,01 X 10^{-5}) (fig. 3). Corelaţiile între nivelul socio-economic, statusul marital şi paritatea mamei nu au demonstrat asociaţii statistic semnificative (r = - 0,1, respectiv r = 0,2).

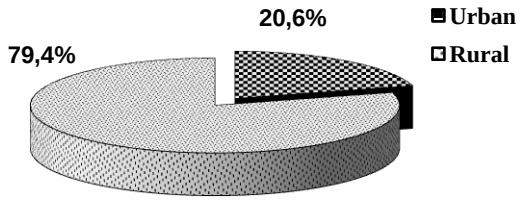

Fig. 2. Frecvenţa subiecţilor incluşi în studiu după mediul de proveniență

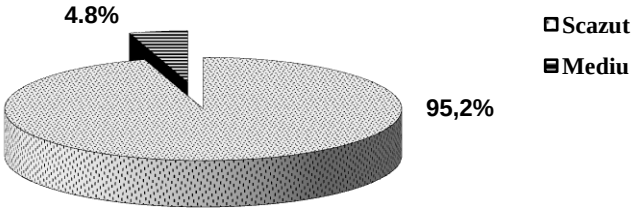

Fig. 3. Distribuţia subiecţilor incluşi în studiu în funcţie de nivelul socio-economic

Cei mai mulţi dintre sugari (40 - 63,4%, p = 0,01 X 10^{-5}) au avut mame cu nivel educaţional scăzut (analfabet şi elementar) (fig. 4), casnice (56 - 88,9%, p< 0,01 X 10^{-5}).

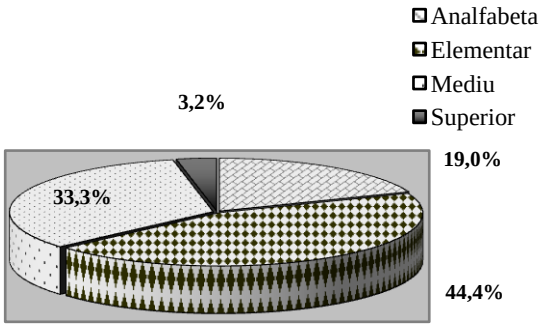

Fig. 4. Distribuţia nivelului educaţional al mamelor subiecţilor incluşi în studiu

Din antecedentele personale fiziologice am remarcat că marea majoritate au fost născuţi în maternitate (56 – 88,9%, p < 0,01 X 10^{-5}), pe cale naturală (44 – 69,8%, p = 0,008 X 10^{-3}) şi peste jumătate din cazuri au avut o vârstă gestaţională mai mică de 37 de săptămâni (35 - 55,55%, p = 0,001), o greutate la naştere sub 2500g şi o talie la naştere mai mică de 47 cm (37 - 58,74%).

Anamneza efectuată la internarea în secţie a relevat prezenţa antecedentelor patologice la un număr semnificativ de sugari (45 - 71,4%) (p = 0,01 X 10^{-4}).

Analizând tipul de alimentaţie administrată sugarilor anterior internării am remarcat că 80,96% (51 sugari) au fost alimentaţi artificial de la naştere, cu biberonul (p = 0,01 X 10^{-5}), în timp ce numai 12 sugari (19,04%) au primit alimentaţie naturală pentru foarte scurt timp (în medie 3 săptămâni), ulterior fiind alimentaţi artificial. Din cei 19 sugari care ar fi trebuit să primească anterior internării o alimentaţie diversificată (complementară), în 13 cazuri (68,42%) s-a efectuat o diversificare incorectă.

Durata medie de spitalizare pentru lotul luat în studiu a fost de 34,15 zile (cu variaţii între 13 – 69 zile), timp în care s-a obţinut un spor ponderal mediu de 895,68 g, între cei doi factori existând o corelaţie pozitivă puternică (r = 0,9).

Studiul scorului Z atât la internarea în secţie cât şi la externare a evidenţiat îmbunătăţirea valorilor medii ale acestuia de la – 4,35 la – 3,54 în ceea ce priveşte greutatea pentru vârstă, de la – 2,93 la – 2,30 referitor la talia pentru vârstă şi de la – 1,53 la – 0 ,70 în cazul greutăţii pentru talie.

Analiza statistică a evidenţiat existenţa unei corelaţii pozitive puternice (r = 0,87) între nivelul socio - economic şi valorile scorului Z greutate pentru vârstă efectuate la internarea în secţie. De asemenea, am obţinut o corelaţie pozitivă puternică (r = 0,97, respectiv r = 0,9) între tipul de alimentaţie pe durata internării şi valorile la externare ale scorului Z (greutate pentru vârstă, talie pentru vârstă). Între durata medie de spitalizare şi scorul Z al taliei pentru vârstă efectuat la externare corelaţia pozitivă a fost moderată (r = 0,55).

DISCUŢII

Derularea acestui studiu este motivată

de menţinerea unui procent ridicat de sugari cu malnutriţie în ţara noastră (7).

Deşi aproximativ jumătate dintre sugarii luaţi în studiu aparţin unor familii organizate, cu un număr redus de copii, proveniența din mediul rural asociată cu şcolarizarea redusă şi statutul de mamă casnică justifică de ce nivelul socio-economic scăzut reprezintă principalul factor de risc în apariţia malnutriţei (11).

Marea majoritate au fost născuţi în maternitate, predominând naşterea pe cale naturală, dar considerăm că se menţine deosebit de ridicat procentul naşterilor în afara unităţilor spitaliceşti (11,1%), comparativ cu un procent de 2% la nivel naţional (12), explicabil prin nivelul educaţional scăzut şi implicit prin educaţia sanitară redusă.

Peste jumătate dintre sugarii incluşi în lotul de studiu până în prezent au fost născuţi la o vârstă gestaţională mai mică de 37 de săptămâni, cu o greutate mai mică de 2500g şi o talie mai mică de 47cm, ceea ce confirmă datele din literatură potrivit cărora naşterea prematură şi greutatea mică la naştere reprezintă factori favorizanţi în apariţia malnutriţiei (13).

Am remarcat apariţia mai frecventă a PEM la grupa de vârstă 5 – 24 de săptămâni, explicabilă prin erorile de alimentaţie: absenţa administrării sau administrarea pe o durată redusă (3 săptămâni) a alimentaţiei naturale, alimentaţia artificială incorectă prin imposibilitatea procurării unor formule de lapte corespunzătoare vârstei sau prin diluarea excesivă a acestora, diversificarea precoce şi/sau incorectă.

Subliniem astfel necesitatea îmbunătăţirii educaţiei mamelor în ceea ce priveşte importanţa alimentaţiei naturale în primele luni de viaţă, a cunoaşterii tehnicii de preparare a formulelor de lapte precum şi a etapelor de diversificare.

Antecedentele patologice prezente într-un procent ridicat (71,4%), concordant cu studiile care subliniază rolul de factor de risc al acestora în apariţia PEM la sugar (14), au impus spitalizări anterior internării în Secţia Recuperare Pediatrică.

Analiza valorilor medii ale scorului Z greutate pentru vârstă şi ale scorului Z talie pentru vârstă la internare subliniază o afectare importantă a acestor indicatori antropometrici potrivit criteriilor OMS (15).

În acelaşi timp valorile medii ale scorului Z greutate pentru talie la internare evidenţiază o afectare mai redusă, justificată de ritmul mai lent de recuperare a taliei la sugarii ce au avut la naştere valori mici ale acestui parametru.

La externare se remarcă o ameliorare mai accentuată a valorilor scorului Z greutate pentru vârstă şi greutate pentru talie, comparativ cu valorile talie pentru vârstă, argumentată de un spor ponderal mediu considerabil (895,68 g) pe o durată medie de spitalizare de 34,15 zile, durată ce nu se poate asocia cu un spor statural la fel de important.

Îmbunătăţirea valorilor acestor indicatori antropometrici la externare subliniază importanţa administrării unei alimentaţii corespunzătoare vârstei şi greutăţii precum şi a asigurării unor condiţii optime de îngrijire.

CONCLUZII

Nivelul socio-economic scăzut reprezintă principalul factor de risc în apariţia malnutriţiei la sugari, în special la cei proveniţi din mediul rural. Considerăm deosebit de importantă abordarea malnutriţiei şi din punct de vedere social, nu doar medical, deoarece revenirea sugarului în acelaşi mediu familial defavorizat are ca rezultat reapariţia malnutriţiei.

Rezultatele obţinute până în prezent confirmă că şi greutatea mică la naştere constituie un alt factor de risc pentru malnutriţie.

Administrarea unei alimentaţii necorespunzătoare afectează cel mai sever statusul nutriţional la grupa de vârstă 5 – 24 săptămâni.

Antecedentele patologice reprezintă, de asemenea, un factor de risc în apariţia PEM.

Acest studiu subliniază importanţa îmbunătăţirii asistenţei medicale primare, în special în mediul rural, în vederea asigurării unui status nutriţional adecvat sugarilor, pentru a întrerupe astfel cercul vicios malnutriţie – infecţie – malnutriţie.

RANKL/RANK/OPG MOLECULAR COMPLEX – CONTROL FACTORS IN BONE REMODELING IN PSORIATIC ARTHRITIS

Camelia Ciacli , Maria Puşchiță
„Vasile Goldis'' Western University, Arad
Department of Internal Medicine and Immunology

RANKL/RANK/OPG MOLECULAR COMPLEX – CONTROL FACTORS OF BONE REMODELING IN PSORIATIC ARTHRITIS (Abstract): **Aim**: To investigate the blood levels of bone remodeling factors (RANKL, OPG and Bone-ALP) in psoriatic arthritis patients. **Material and methods:** Included in this study were 27 patients with psoriatic arthritis (CASPAR classification criteria) and 20 healthy subjects. The RANKL , OPG and Bone-ALP levels have been quantified by ELISA method. **Results:** Peripheral blood concentrations were higher in psoriatic arthritis than in the healthy subjects, and a strong negative correlation between RANKL and OPG and between RANKL and Bone-ALP was also found. **Conclusions**: The increase in OPG and Bone-ALP serum level is strongly related to the increase in RANKL serum level in patients with psoriatic arthritis. The increase in OPG and Bone –ALP serum level induces the production of bone matrix parallel to the bone destruction mediated by RANKL. The follow up of the patients with psoriatic arthritis by early RANKL, OPG and Bone-ALP serum level determinations, and of bone metabolism markers (with specific role in bone remodeling), allows an accurate evaluation of disease activity and, in the future, could be a criterion for the initiation of specific, targeted treatment. **Key words**: BONE REMODELING, RANKL/RANK/OPG MOLECULAR COMPLEX, PSORIATIC ARTHRITIS

The recently discovered fact that psoriatic arthritis represents itself a unique pathology increased the concern for studying this disease in the past years.

The psoriatic arthritis is a chronic inflammatory disease accompanying psoriasis, characterized by bone proliferation and resorption, particularly affecting the tendons, the articulations and the enteses (the articular capsular insertion) (1). Psoriatic arthritis, together with rheumatoid arthritis, is one of the most frequent causes for handicap in patients' social and familial activities. In twenty five procents of patients labor inability was found in 6 years, and in 50% of patients in 10 years (2). In order to demonstrate this real problem in the literature, one French study reveals that the costs for the psoriatic arthritis (in France) is estimated to 5,2-6,5 billions euro (3). Concerning all these, an important objective seems to be the early identification of patients with major risk for articular destruction and early therapeutic intervention.

Remodeling, the bone reconstruction, comes immediately after its formation, being more intense in utero. Frost, in 1964, was the first that described the bone remodeling (4).

Bone remodeling is the cellular and mor-

phologic support for the bone turnover; it keeps in good shape the biomechanical status of the skeleton. In adults, in which the growth is finished, the bone mass and structure are kept constant in time, although the bone remodeling is continue, by an exact balance between the resorbtion and formation of bone in the entire skeleton (5,6,7).

In normal conditions, the resorbed bone is replaced by an equal amount of new bone, so that after each cycle of bone remodeling, the total mass of bone stays constant. This remodeling permits the maintenance of the bone mass constant during the normal adult life. A good bone remodeling needs close interactions between the bone cells, bone marrow and the matrix; these interactions also need soluble factors synthesized by the cells or being available within the matrix.

The imbalance of this process have consequences on the bone architecture and the bone mass, and could lead, for a long period of time, to a loss of integrity in the skeleton structure and to fractures, all these being important causes of morbidity and mortality in ageing, or causes of different diseases that sustain this imbalance.

The bone remodeling regulation is done by many factors:

- RANKL (Receptor activator of nuclear factor NF-kB ligand) also known as ODF (osteoclast differenciation factor), OPGL (osteoprotegerin ligand) or TRANCE (TNF related activation induced cytokine)
- RANK (Receptor activator of NF-kB): this receptor is situated on the pre-osteoclasts cellular membrane; it is also known as ODAR (osteoclast differentiation activating receptor).

OPG (osteoprotegerina) is a natural "decoy" receptor of RANKL; it's also known as OCIF (osteoclast inhibiting factor).

These factors regulate the bone remodeling in psoriatic arthritis, rheumatoid arthritis, post-menopausal osteopenia, osteoporosis in inflammatory chronic reumatisms, in gums pathology in which the alveolar bone is resorbed, and in bone metastasis (6,7).

MATERIAL AND METHODS

The trial includes individuals in two groups:

- **Group 1** (patients with psoriatic arthritis diagnosed by the CASPAR criteria - The **Cla**ssification **C**riteria for **P**soriatic **A**rthritis). It includes 27 patients (n=27), 15 men and 12 women, aged between 27 and 50.
- **The healthy group** includes 20 individuals (n=20), 9 women and 11 men, aged below 50 and without any rheumatism, infectious, neoplasic or autoimmune disease.

The two groups have been investigated in CDMT Laboratory in Timisoara between 2004 and 2007.

- **Inclusion criteria**: patients aged 27-50, diagnosed with psoriatic arthritis by CASPAR criteria (The **Cla**ssification **C**riteria for **P**soriatic **Ar**thritis) for at least 36 months, being in an acute stage of the disease and lacking an anti-inflammatory treatment for at least one month before inclusion. A complete clinical general inspection and paraclinical investigations have been done for these patients, with the aim to exclude an associated autoimmune disease, a cancer disease or a systemic infection.
- **Exclusion criteria**: patients with:
  - ankilopoetic spondilitis
  - Reiter Syndrome
  - Other bone diseases diagnosed by a detailed history, the clinical general examination, the paraclinical investigations (Pa-

get disease, Cushing Syndrome, Multiple Myeloma, Hodgkin's Disease etc)

– alcohol consumers

– intestinal inflammatory diseases (Crohn Disease etc)

– malnutrition

– vitamin D deficiency or any treatment that affects the bone metabolism

– patients that received glucocorticoids or methotrexate treatments in the last 12 months

– other diseases that need long term treatment with glucocorticoids (more than 6 months)

– patients that received dietary supplements with Calcium or Vitamin D

– sustained physical activity in the last 12 months

– women aged below 40 in early menopausa of different etiology (chirurgical or medical).

The RANKL and OPG serum levels were quantified by sandwich Elisa immunoenzimatic assay (Enzyme Linked Immuno Sorbant Assay).

THE AIM OF THE STUDY

Evaluation criteria:

- **Bone resorbtion** evaluation by the determination of RANKL serum level, marker of bone resorbtion in bone remodeling.
- **Osteosynthesis** evaluation by the determination of serum level of OPG, marker of bone synthesis in bone remodeling.
- The **correlation of RANKL** (marker of bone resorbtion) and **OPG** (marker of bone synthesis) serum levels.

Statistical analysis

The graphics and the statistical analysis in this study were done by use of Microsoft Office Excel 2007. We used:

– The elements of descriptive statistics: mean and standard deviation (mean ± DS);

– The elements of intererential statistics: the t´ Student test and the Pearson test.

– **The t´ Student test** was used for the comparison of data belonging to the psoriatic arthritis group comparative to the healthy group. The values of the p_1 were calculated (group 1 and healthy group) $p<0.05$ has statistically semnificative value.

– **The Pearson test** awas used for the comparison of data within the same analised group. The values of the r_1 were calculated.Y $r>0.5$ has good correlation (positive or negative)

RESULTS

RANKL serum levels were assessed by enzyme linked immunosorbent assay (ELISA).

In group 1 (psoriatic arthritis), the RANKL serum level was between 36.35 and 68.99 pg/ml (mean was 51.98±10.74 pg/ml; $p_1<0.003$- ES, statistically semnificative compared to the healthy group).

In the healthy group, the RANKL serum level was between 29.65 and 37.14 pg/ml (mean was 32.46±3.03 pg/ml) (Table I, Fig. 1).

TABLE I

RANKL serum levels in psoriatic arthritis comparative to those in the healthy group

Parameter (mean ± DS)	Group 1 (psoriatic arthritis)	Healthy Group
RANKL serum level (pg/ml)	51.98±10.74 p<0,003	32.46±3.03

(Table I. Increased RANKL serum levels: $p_1<0.003$- ES, ES - intense statistical significance comparative to the healthy group)

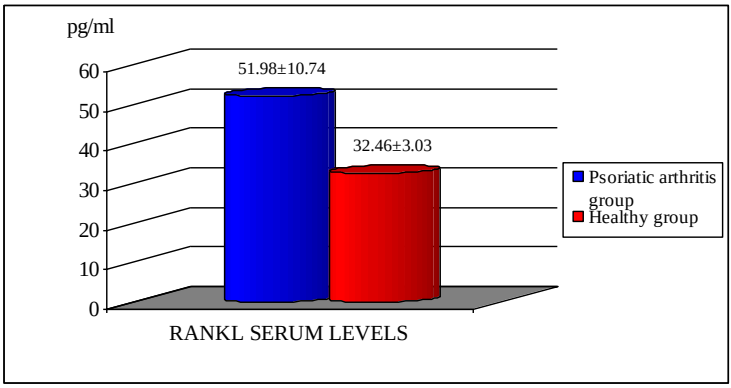

Fig. 1. The comparison of RANKL serum levels in analyzed groups
(Figure 1. Increased RANKL serum levels: $p_1<0.003$- ES in psoriatic arthritis group, ES- intense statistical significance comparative to the healthy group)

After processing the data, the results show an increase in RANKL serum levels in lot 1 comparative to the healthy group, due to the increase in bone destruction: the mean increased with 160.13 %, up to 51.98±10.74 pg/ml.

The **OPG serum levels** were assessed by enzyme linked immunosorbent assay (ELISA).

In group 1 (psoriatic arthritis**),** the OPG serum level was between 33.18 and 48.42 pg/ml (mean was 38.05±4.89 pg/ml; $p_2<0.002$- ES, intense statistical significance comparative to the healthy group).

TABLE II

The OPG serum levels in group 1 (patients with psoriatic arthritis) comparative to those in the healthy group

Parameter (mean ± DS)	Group 1 (psoriatic arthritis)	Healthy Group
OPG serum level (pg/ml)	38.05±4.89 $p_2<0.002$	28.06±1.39

(Table II. Increased OPG serum levels: $p_2<0.002$- ES, ES- intense statistical significance comparative to the healthy group)

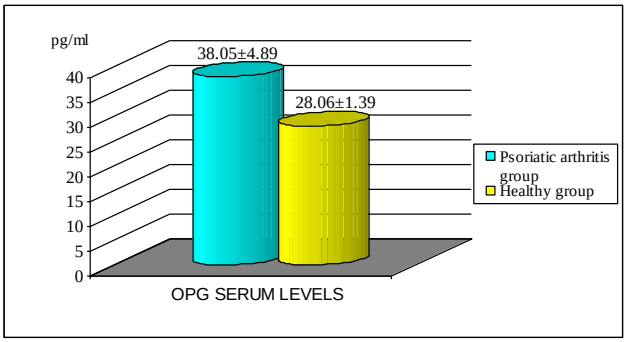

Fig. 2. The comparison between OPG serum levels in analyzed groups
(Figure 2. Increased OPG serum levels: $p_2<0.002$- ES in psoriatic arthritis group, ES- intense statistical significance comparative to the healthy group)

TABLE III

Comparison between the RANKL serum level and the OPG serum level in psoriatic arthritis patients.

Parameter (mean ± DS)	Serum RANKL (pg/ml)	Serum OPG (pg/ml)
Group 1 (n=27)	51.98±10.74 p_1<0,003	38.05±4.89 p_2<0,002 r_2= -0.87

(Table III: Increased RANKL and OPG serum levels in psoriatic arthritis: p_2< 0.002-E S, intense statistical significance in group 1, p_1< 0.003-ES, intense statistical significance in group 1 comparative to the healthy group and in strong negative correlation, r_2= -0.87).

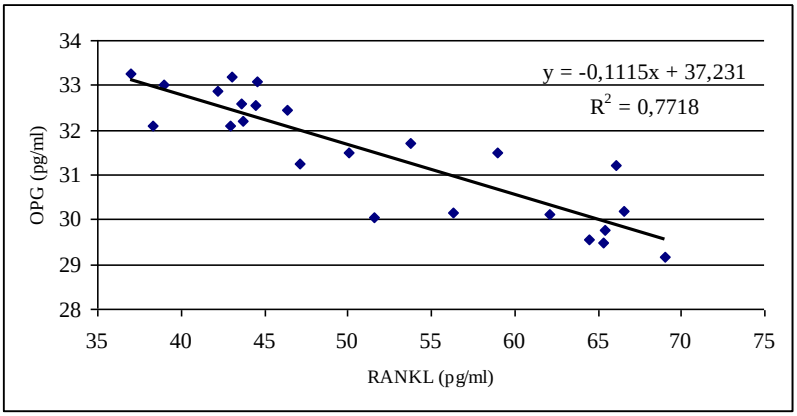

Fig. 3. The correlation between OPG and RANKL serum levels in psoriatic arthritis patients. (Figure 3.The RANKL serum level showing strong negative correlation with OPG serum level, r_2 = -0.87, R_2^2= 0.7718).

In the healthy group, the OPG serum level was between 26.65 and 33.18 pg/ml (mean was 28.06±1.39 pg/ml).

After processing the data the results show an increase in OPG serum levels in group 1 comparative to the healthy group, due to the increase in bone synthesis. The mean increased with 135.60 % up to 38.05±4.89 pg/ml.The data processing showed a strong negative correlation between OPG and RANKL serum levels in psoriatic arthritis patients: r_2= - 0.87 (R_2^2= 0.7718 in group 1).

DISCUSSION

The tendency to developed bone erosions in psoriatic arthritis is well known and manifests radiological as massive loss of articular space, big bone lesions, bone erosions radiologicaly described as “pencil head” and the resorbtion of the distal phalanx(8). The periarticular mineralization is intense and is accompanied by new bone formation in periostatic and ankilotic forms of disease. The presence of bone resorbtion and of new bone formation markers attests the bone remodeling in psoriatic arthritis.

Concerning the fact that the osteoclasts play a role in mediation of bone erosion in rheumatoid arthritis and that the RANKL/ RANK signal is also important in this process, the researchers focused on psoriatic arthritis, too(11).

Studies using anti-RANKL and anti-OPG monoclonal antibodies showed that

RANKL is expressed on the synovial cells, but OPG, which is expressed on the endothelial cells.

These studies demonstrate that RANKL is the key mediator in articular destruction and in bone loss in psoriatic arthritis.

The therapeutic inhibition of RANKL action using osteoprotegerine (OPG), natural "decoy" receptor, completely prevents the bone loss in articular inflammatory diseases and has a benefic effect on the cartilage destruction in all arthritic studied models. The modulation of this system allows the physicians to use a new therapy for stopping the bone loss and to prevent the handicap due to arthritis.

CONCLUSIONS

The final assessment of all data revealed from this study leads to:

– In psoriatic arthritis the RANKL serum level increases due to the activation of osteoclasts and therefore due to bone destruction.

– This increase in RANKL serum level represents a marker for the activity of the disease.

– In psoriatic arthritic patients, the OPG serum level increases more than in normal individuals.

– The increase in OPG serum level represents a marker for the activation of osteosynthesis, which takes place in bone remodeling process in psoriatic arthritis.

– The increase in OPG serum level shows a strong negative correlation with that the increase in RANKL serum level in psoriatic arthritic patients.

– This increase in OPG serum concentration tries to induce the reconstruction of bone matrix, compensatory to the destructive process mediated by RANKL.

– The monitoring of psoriatic arthritis patients by early determination of RANKL and OPG serum levels, bone metabolism markers (they have specific role in bone remodeling), allows a precise evaluation of the disease activity, and, in future, could be a criteria for initializing the specific, targeting therapy.

NOUTĂȚI

NOI MODALITĂȚI DE DIAGNOSTIC ÎN INFECȚIILE CU *KINGELLA KINGAE*

Kingella kingae este frecvent implicată în infecțiile ostearticulare la copil. Deoarece metodele de izolare clasice sunt dificile, s-a încercat standardizarea metodelor de diagnostic prin tehnici de biologie moleculară. În acest scop s-a folosit ca secventă de interes toxina RTX, genomul bacterian nefiind secvențiat până în prezent. Scopul studiului a fost dezvoltarea unei metode rapide, sensibile şi specifice utilă pentru a stabili diagnosticul etiologic al acestor infecții. Au fost aplicate două metode Real Time PCR (în sistem Taq Man şi SYBR green), ambele având ca scop indentificarea secvențelor nulceotidice rtxA. Sensibilitatea şi specificitatea metodelor a fost evaluată folosind 67 tulpini bacteriene (31 au fost *Kingella kingae).* Apoi, 52 probe pozitive şi/sau negative în cultură şi/sau PCR au fost testate folosind aceste două tehnici. Ulterior s-a folosit tehnica PCR "în cuib" şi secvențierea tulpinilor izolate pentru a confirma prezența *Kingella kingae* în probele luate în lucru. Rezultatele obținute au demonstrat acuratețea metodelor mai sus prezentate în stabilirea diagnosticului etiologic (Lehours P, Freydière A, Richer O et al, The rtxA Toxin Gene of Kingella kingae: a Pertinent Target for Molecular Diagnosis of Osteoarticular Infections. *J Clin Microbiol* 2011; 49: 1245-1250).

ACTIVE DETECTION OF FRAILTY IN THE ROMANIAN ELDERLY POPULATION - THE GFI QUESTIONNAIRE METHOD (Abstract): The notion of frailty has gradually gained hold in medical discourse through the identification of an elderly population at risk of death or of events affecting their autonomy. This state of vulnerability is a central feature of old age, a new concept in medicine, leading to decreased quality of life, dependency and death. **Aim:** To identify frailty score and factors involved in elderly patients through the Romanian version of the Groningen fragility indicator (GFI) questionnaire among the independently living elderly in Romania. **Material and methods:** Observational study which included 100 persons aged 65 to 74 years, randomly selected from primary care practices in Romania in the interval March-April 2017. **Results**: A moderate to severe degree of frailty was identified in the study cases (mean score 4.08). The mean frailty score was significantly higher at the age of 70 years old compared to age group 60-69 (4.58 *vs*. 3.58, p = 0.036). The study showed that frailty score was increased by the following comorbidities: stroke, COPD, chronic urinary infection, cataracts. **Conclusions**: Frailty score can be easily determined in primary care practices, leading to an early identification of the elderly requiring geriatric assessment and treatment. **Keywords:** FRAILTY DETECTION, STATE OF VULNERABILITY, ELDERLY POPULATION.

Frailty syndrome is reported to affect 7% of the elderly patients aged over 65 years, and 25–40% of those aged 80 years old or over. The borders between age and frailty appear to be so indistinct that it is widely supposed that at a specific age, all people become frail (1). Because frailty is strongly related to adverse outcomes, it is important to identify the persons at risk for frailty and to detect it in an early stage.

The Romanian population is one of the fastest aging populations in Europe, whereas the total population is simultaneously decreasing rapidly. During the last decade, health policy has been directed towards strengthening the role of primary health care, to reduce (unnecessary) hospital admissions and to encourage preventive screening programs (2).

The Romanian elderly population has been confronted with dramatic changes in social security (pension cuts and limited free access to health care services) as well as in the quality of health care (waiting lists, lack of personnel and facilities, co-payments). The need for pro-active health

programs such as screening for frailty may be evident (3).

Several studies have proposed instruments to measure frailty. Some are complex, others simple. One of these studies compared the feasibility, reliability and validity of frailty assessment instruments, i.e. the Groningen Frailty Indicator (GFI), the Tilburg Frailty Indicator and the Sherbrook Postal Questionnaire (4, 5). Based on this comparison, the GFI has demonstrated the highest internal consistency and construct validity (5, 6, 7).

The GFI questionnaire can be used to assess frailty in the non-institutionalized Romanian elderly since 2014.

MATERIAL AND METHODS

This observational study was conducted in a series of 100 patients aged 65-74 years old who presented to their primary care physician between March 1st to April 30th, 2017. Inclusion criteria were: age over 65 years, free consent to complete the questionnaire.

The Romanian version of GFI questionnaire was used to determine the overall fragility status using 3 areas: Daily Activity, Health Problems and Psychological Functions. It is also 15 items screening instrument.

The main objective was to identify frailty score in patients in the target group and the secondary objective was considered a personalized approach to elderly patients: risk assessment, prevention and early identification of factors involved in the occurrence of frailty in the elderly: biological, psychological/cognitive, social/familial.

The standard score scale ranges from 0 to 15, a small score signifying robustness, and a high score a state of vulnerability.

The obtained data were statistically analyzed using *SPSS 18* software.

RESULTS

Descriptive indicators revealed a higher number of women (77 patients) versus men (23 patients), M/F sex ratio 1:3. Data on patient age did not reveal significant gender differences in the mean age (69 years; p=0.758). In terms of civil status: 60% married *vs.* 39% divorced/widowed and 1% unmarried.

A score of 4 or more is considered an indicator of moderate to severe frailty.

TABLE I

Descriptive score indicators for frailty depending on the socio-demographic characteristics

Characteristics	N	Average	Standard deviation	Standard error	Confidence interval 95%		Min	Max	Test t-Stud. p
					-95%CI	+95%CI			
Number of patients	100	4,08	2,40	0,240	3,60	4,56	0	11	-
Gender									0,934
Male	23	4,04	3,30	0,687	2,62	5,47	0	11	
Female	77	4,09	2,09	0,238	3,62	4,56	1	11	
Age groups (years)									
60-69	50	3,58	2,46	0,348	2,88	4,28	0	10	**0,036**
70-79	50	4,58	2,25	0,318	3,94	5,22	1	11	
Civil Status									0,660
Married	60	4,17	2,68	0,345	3,48	4,86	0	11	
Unmarried	40	3,95	1,93	0,306	3,33	4,57	1	8	

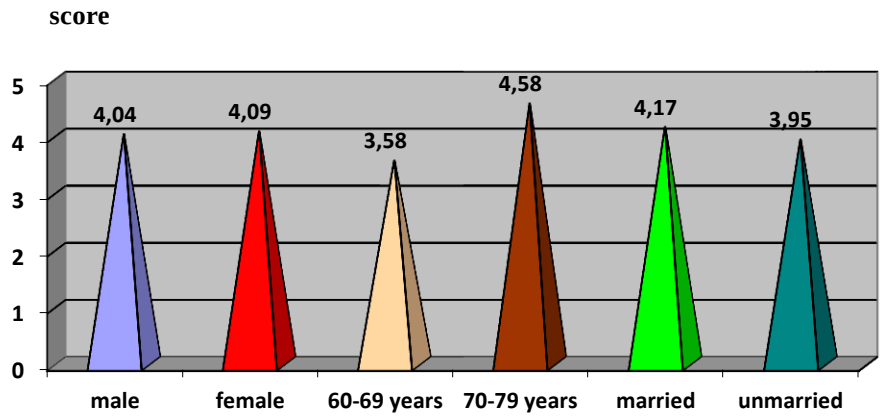

Fig. 1. Average frailty score depending on socio-demographic characteristics

The average score (4.08 ± 2.40) of the study patients revealed moderate to severe frailty. There were no significant gender differences in mean frailty scores (M=4.04 *vs.* F=4.09, p = 0.934).

The mean frailty score was significantly higher in those over 70 years compared to age group 60-69 (4.58 *vs.* 3.58, p = 0.036).

The average frailty score was slightly lower in unmarried, divorced or widowed compared to married patients (4.17 *vs.* 3.95, p = 0.660) without statistical significance (tab. I, fig.1).

The presence of the following comorbidities significantly increased the frailty score: stroke (p=0.036), Parkinson's disease (p=0.019), COPD (p= 0.015), chronic urinary infection (p=0.042), cataracts (p=0.025), lumbar disc disease (p= 0.021).

DISCUSSION

Frailty of the elderly is a complex concept with multifactorial determinations: age, disease/comorbidities, marital status, family and social context. The frailty score increases with age, determining it with the GFI questionnaire being also a good tool for detecting frailty in the general population (8).

In our study the percentage of subjects identified as frail with the help of the GFI questionnaire was high, with a mean and median frailty score of 4.04/4.09 among the old Romanians (*n* = 100; mean age 69 years).

Peters *et al.* (7) reported a median score of 3 for independent-living old persons (*n* = 168) and a score of 6 for persons living retirement or nursing homes. Also, Metzelhin *et al.* (4) and Drubbel *et al.* (6) found a mean score of 3.8 (*n* = 532; mean age 77 years) and 3.2 (*n* = 623; mean age 73 years), respectively, among independent-living old persons. Our findings indicate that independent-living old Romanians are frailer.

The frailty score increases in direct proportion to the deterioration in health. Wong *et al.* (9) recently reported that among community dwelling seniors who are frail 82% have comorbidities. Findings suggest that frailty may be caused by mechanisms that are shared with chronic diseases once the diseases have reached a severe or advanced stage.

These findings agree with our study re-

sults showing that comorbidities like stroke, Parkinson's disease, COPD, chronic urinary tract infection, cataracts, and lumbar disc disease significantly increase the frailty score.

CONCLUSIONS

We conclude that the predictive value of GFI in primary health care is limited, which is in line with other findings, but identifying the frailty status through the questionnaire among elderly in primary care requires complex outpatient geriatric assessment.

The frailty score can be calculated easily in primary care practices, leading to an early identification of frailty status. The benefits of this determination are: prevents medical-social events: comorbidities, addiction, immobilization; early identification of early elderly people requiring geriatric evaluation and/or treatment; personalized and targeted (biopsychosocial) intervention that improves the quality of life.

ACKNOWLEDGEMENTS

The fieldwork of this project was executed in collaboration with the primary care practitioners in the Braila county, Romania. The Groningen Frailty Indicator was translated (forwards and backwards) by Media Dom Express SRL, Romania.

2. Pediatrics Department

WILSON'S DISEASE: A CHALLENGING DIAGNOSIS. CLINICAL MANIFESTATIONS AND DIAGNOSTIC PROCEDURES IN 12 PATIENTS (Abstract): Wilson disease is a neurodegenerative disease of copper metabolism. The genetic defect, localized to chromosome arm 13q, has been shown to affect the copper-transporting adenosine triphosphatase (ATPase) gene (*ATP7B*) in the liver. Our aim was to study the clinical and laboratory characteristics of 12 children and young adults diagnosed with WD and point out the diagnostic difficulties. **Material and method**: We retrospectively analyzed the patients diagnosed with Wilson's disease between 2001 and 2009 diagnosed in Constanţa County Emergency Hospital. Evaluation included detailed physical examination, conventional laboratory testing, genetic analysis, and liver biopsy. **Results**: Patients with hepatic symptoms showed a considerably earlier onset of symptoms and a shorter diagnostic delay before definitive diagnosis than those with neuropsychiatrical symptoms. The mean age at diagnosis was 9.12 +/- 2.59 years (range 5 years-20 years). 10 patients were symptomatic, 6 were referred because of abnormal liver function test results and/or hepatomegaly, 4 had neuropsychiatrical symptoms and 2 received their diagnoses after family screening. Hepatic copper concentration was between 250 and 1200 micrograms/g. 4 patients had liver cirrhosis, five chronic hepatitis and one had massive hepatic necrosis on necropsy. Any person with recurrent hepatic disease and unexplained neurological symptoms should be investigated to have Wilson's disease. **Conclusions**: Detection of WD in children and young adults remains very difficult. The most important investigation is liver biopsy with the assessment of liver copper. Genetic analysis may help in doubtful cases. **Key words**: WILSON'S DISEASE, DIAGNOSTIC PROCEDURES, CLINICAL MANIFESTATIONS

Wilson disease, or hepatolenticular degeneration, is a neurodegenerative disease of copper metabolism (1). In 1912, Wilson first described it as a familial disorder associated with neurological symptoms and cirrhosis. In 1956, Walshe first treated patients with the chelating agent penicillamine (2, 3).

The genetic defect, localized to chromosome arm 13q, has been shown to affect the copper-transporting adenosine triphosphatase (ATPase) gene (*ATP7B*) in the liver[3]. Patients with Wilson disease usually present with liver disease during the first decade of life or with neuropsychiatric illness during the third decade[1]. The diagnosis is confirmed by measurement of serum ceruloplasmin, urinary copper excretion, and hepatic copper content, as well as the detection of Kayser-Fleischer rings (1, 2).

Wilson's disease may exhibit a variety of clinical symptoms, the most common being liver disease and neuropsychiatric disturbances (4, 5, 6). Wilson's disease typically begins with a presymptomatic period, during which copper accumulation in the liver causes subclinical hepatitis, and progresses to liver cirrhosis and development of neuropsychiatrical symptoms. The type of hepatic and

neurological symptoms can be highly variable. Wilson's disease may also present as fulminant hepatic failure with an associated Coombs-negative haemolytic anaemia and acute renal failure.

OBJECTIVES

Wilson disease (WD) has a wide spectrum of clinical manifestations. Affected children may be entirely asymptomatic making the diagnosis very difficult. Our aim was to study the clinical and laboratory characteristics of 12 children and young adults diagnosed with WD and point out the diagnostic difficulties in this population.

MATERIAL AND METHOD

Because the disease affects mostly young patients, the median age of our patients was between 8 and 20 years. We retrospectively analyzed the patients diagnosed with Wilson's disease between 2001 and 2009 diagnosed in Constanta County Emergency Hospital. Clinical and laboratory data were collected from 12 consecutive children and young adults with WD. Evaluation included detailed physical examination, conventional laboratory testing, genetic analysis, and liver biopsy.

Clinical manifestations

We found 12 patients, in whom the diagnosis of Wilson's disease was challenging. In this case series, there were 6 patients with recurrent hepatic disease and 4 patients with hepatic disease and unexplained neurological symptoms Liver disease occurred in more than a half of the patients.

Liver disease

Wilson disease manifested as liver disease in children and adolescents, peaking at ages 10-13 years, and as neuropsychiatrical illness in young adults aged 19-20 years.

Neurological and psychiatrically symptoms

We identified 4 adult patients with neurological and psychiatric symptoms at the beginning. Frequent early symptoms included : difficulty speaking, excessive salivation, ataxia, masklike facies, clumsiness with the hands, and personality changes.

The most common presenting neurological feature was asymmetric tremor, occurring in approximately half of individuals with Wilson disease. The character of the tremor is variable and may be predominantly resting, postural, or kinetic.

In our case series, most adult patients who presented with neuropsychiatrical manifestations have also cirrhosis.

Late manifestations (now rare because of earlier diagnosis and treatment) included : dystonia, spasticity, grand mal seizures, rigidity, and flexion contractures, encountered in more than a half adult patients.

We describe four distinct diagnostic categories based on patients' major neurological findings : parkinsonian, pseudosclerotic, dystonic and choreoathetotic.

Ophtalmological examination

Kayser-Fleischer rings are formed by the deposition of copper in the Descemet membrane in the limbus of the cornea. The color ranged from greenish gold to brown ; when well developed, rings was readily visible to the naked eye or with an ophthalmoscope set at +40. When not visible to the unaided eye, the rings were identified using slit-lamp examination or gonioscopy.

Kayser-Fleischer rings were observed in up to 90% of adults with symptomatic Wilson disease with neurological manifestations. In children with neurological Wilson's disease the Kayser-Fleisher ring was present in only 60% of cases.

Musculo-skeletal manifestations

Musculo-skeletal involvement is a common feature of Wilson disease. More than a half of our patients exhibited osteopenia on conventional radiological examination.

The arthropathy of Wilson disease is a degenerative process that resembles premature osteoarthritis. Symptomatic joint disease occurred at 3 patients, usually late in

the course of the disease, frequently after age 25 years. The arthropathy generally involved the spine and large appendicular joints, such as knees, wrists, and hips.

Hematological findings

Hemolytic anemia was a recognized complication of the disease at one patient.

Renal disease

The frequency of renal manifestations was variable. Clinically, some patients resembled those with Fanconi syndrome, demonstrating defective renal acidification and excess renal losses of amino acids, glucose, fructose, galactose, pentose, uric acid, phosphate, and calcium. In one patient who presented with Fanconi Syndrome-like manifestations, the dignosis was delayed for five years, until the ataxia became apparent. Urolithiasis, found in one patient with Wilson disease, may be the result of hypercalciuria or poor acidification.

RESULTS

The mean age at diagnosis was 9.12 +/- 2.59 years (range 5 years-20 years). 10 patients were symptomatic, 6 were referred because of abnormal liver function test results and/or hepatomegaly, 4 had neuropsychiatrical symptoms and 2 received their diagnoses after family screening.

All patients presented with hepatic disease. 4 patients also had neurological involvement. Hepatic copper concentration was between 250 and 1200 microg/g. 4 patients had liver cirrhosis, 5 chronic hepatitis, and 1 had massive hepatic necrosis on necropsy.

5 patients had both Kayser-Fleischer ring and decreased serum ceruloplasmin levels, 6 had urinary copper excretion after penicillamine challenge >1600 microg/24 hours, and 2 had liver copper content >250 microg/g dry weight. Of the remaining 6 patients, 5 had both low serum ceruloplasmin $<$ or $=20$ mg/dL and increased urinary copper excretion, >75 microg/24 hours before, or $>$ 1000 microg/24 hours after penicillamine challenge. In 1 patients the diagnosis was confirmed by genetic analysis.

Hepatic involvement manifested in four ways : acute hepatitis, chronic active hepative hepatitis, cirrhosis and fulminant hepatitis. Recurrent episodes of liver disease ocurred in a variable interval (months to years), until neurological symptoms developed. At one patient, the fulminant liver injury leads to sudden release of copper in the bloodstream and hemolytic anemia with negative Coomb's test. This was a life threatening condition and conducted to death. In 1 patient the diagnosis of Wilson's disease was established because they were brothers and sisters of known patients.

The most common presenting neurological feature was asymmetric tremor, occurring in approximately half of individuals with Wilson disease. The character of the tremor is variable and may be predominantly resting, postural, or kinetic.

The patient in the parkinsonian group was distinguished by paucity of expression and movement.

The patient in the pseudosclerotic group had tremor resembling multiple sclerosis.

The patients in the dystonic group were characterized by hypertonicity associated with abnormal limb movements.

The patients in the choreic group were predominantly characterized by choreoathetoid abnormal movements associated with dystonia.

The majority of patients diagnosed with neurological Wilson's disease presented also with psychiatric features : emotional lability, impulsiveness, disinhibition, and self-injurious behavior.

Although Kayser-Fleischer rings are a useful diagnostic sign, they are no longer considered pathognomonic of Wilson disease unless accompanied by neurological manifestations. They may also be observed in patients with chronic cholestatic disorders, such as partial biliary atresia, primary bil-

iary cirrhosis, primary sclerosing cholangitis, and cryptogenic cirrhosis.

Approximately 90% of all patients with Wilson disease have ceruloplasmin levels of less than 20 mg/dL (reference range, 20-40 mg/dL).

Ceruloplasmin levels was also decreased in 10-20% of *WD* gene heterozygotes, who do not develop Wilson disease and do not require treatment

The urinary copper excretion rate was greater than 100 mg/d (reference range, <40 mg/d) in most patients with symptomatic Wilson's disease.

Hepatic copper concentration

A liver biopsy with sufficient tissue revealed levels of more than 250 mcg/g of dry weight was performed in 2 patients. Special collection vials were used to help avoid contamination.

Genetic diagnosis : Linkage analysis has been used in 3 patients and to screening of family members for an identified mutation detected in the index patient. Using this method we identified 2 asymptomatic siblings.

Imaging Studies

Computed tomography (CT) scan revealed hypodense regions in the basal ganglia (caudate nucleus, putamen, globus pallidus) in all adults patients diagnosed with neurological Wilson's disease. The cranial lesions observed on CT scan were typically bilateral and were classified into two general categories, as it follows :

(1) well-defined, slitlike, low-attenuation foci involving the basal ganglia particularly the putamen

(2) larger regions of low attenuation in the basal ganglia, thalamus, or dentate nucleus

Brain MRI appears to be more sensitive than CT scanning in detecting early lesions of Wilson disease. MRI studies have identified focal abnormalities in the white matter, pons, and deep cerebellar nuclei in 4 patients These lesions, measuring 3-15 mm in diameter, were typically bilateral, appearing with low signal intensity on T1-weighted images and with high signal intensity on T2-weighted images, representing cell loss and gliosis.

Hepatic biopsy

The earliest changes detectable with light microscopy included glycogen deposition in the nuclei of periportal hepatocytes and moderate fatty infiltration. The lipid droplets, which are composed of triglycerides, resembling the steatosis induced by ethanol, were also described in 9 patients who underwent this procedure.

No correlation was found between specific mutations and the disease phenotypic expression. Chelating therapy was well tolerated, and the outcome was satisfactory.

DISCUSSIONS

The presence of Kayser-Fleischer rings and ceruloplasmin levels of less than 20 mg/dL in a patient with neurologic signs or symptoms suggest the diagnosis of Wilson's disease. If a patient is asymptomatic, exhibits isolated liver disease, and lacks corneal rings, the coexistence of a hepatic copper concentration of more than 250 mg/g of dry weight and a low serum ceruloplasmin level is sufficient to establish a diagnosis.

Both the sensitivity and the specificity of urinary copper are suboptimal for use as a screening test ; however, it may be useful to confirm the diagnosis and to evaluate the response to chelating therapy.

One aspect of our study was to discriminate between the age at symptom onset and at diagnosis. Patients with hepatic symptoms showed a considerably earlier onset of symptoms and a shorter diagnostic delay before definitive diagnosis than those with neuropsychiatrical symptoms. Family screening was effective in diagnosing patients with Wilson's disease at an early, and most often asymptomatic or pre-symptomatic, stage of

disease. By family screening, patients were diagnosed an average of 4 years earlier, with an excellent long-term outcome.

The wide spectrum of symptoms and of age at onset in patients with Wilson's disease raised the question whether these features are determined by the type of the ATP7B mutation. The ATP7B mutational analysis showed no clear genotype–phenotype correlations 5.6. However, previously published studies on genotype–phenotype correlations have shown variable results. A recent meta-analysis showed an association of the ATP7B H1069Q mutation with a late neurological presentation in Wilson's disease (7) although the underlying studies are quite (8, 9, 10). Most reports on mutations other than H1069Q show no clear-cut phenotype–genotype correlations (12, 13, 14).

A substantial proportion of the patients developed side effects. This was especially true in D-penicillamine treatment, where severe side effects were recorded in more 30% of all treated patients. In the light of our data, and especially considering that effective alternative drugs available, the role of D-penicillamine as a standard treatment for Wilson's disease must be questioned (15, 16, 17, 18). In our study cohort, development and worsening of neurological symptoms were reported while under treatment with all three drugs (penicillamine, Trientine and Zinc) but most frequently (13.8%) for D-penicillamine. This may be partly as a result of the longer summarized follow-up period for D-penicillamine. Nevertheless, in our opinion, D-penicillamine should not be the drug of choice for patients with neurological symptoms.

CONCLUSIONS

Any person with recurrent hepatic disease and unexplained neurological symptoms should be investigated to have Wilson's disease. Liver disease occurs in half of the patients. It may be manifested in four ways : acute hepatitis, chronic active hepatitis, cirrhosis and fulminant hepatitis. Recurrent episodes of liver disease may occur in a variable interval (months to years) until neurological symptoms develop. Ultimately, all patients develop cirrhosis. The fulminant liver injury may lead to sudden release of copper in the bloodstream and hemolytic anemia with negative Coomb's test. This may be a life threatening condition if not promptly corrected.

The best way to monitor efficacy is to measure serum nonceruloplasmin-bound copper. This is measured by the following formula :

Total serum copper (mcg/dL) - 3[ceruloplasmin (mg/dL)].

The reference range is <15 mcg/dL.

An adjunctive way to monitor efficacy is to measure urinary copper excretion. Urinary chelator levels usually measure 200-500 mcg/day. Urinary zinc levels usually measure <75 mcg/day.

Detection of WD in children and young adults remains very difficult. The most important investigation is liver biopsy with the assessment of liver copper. Genetic analysis may help in doubtful cases.

LINKING THEORY TO PRACTICE: UNDERUSE OF CHRONIC ORAL ANTICOAGULATION IN ATRIAL FIBRILLATION

Alexandra Stoica, Victoriţa Şorodoc*, Cătălina Lionte, Oana Sîrbu, O. R. Petriş, A. Ceasovschih, L. Şorodoc

LINKING THEORY TO PRACTICE: UNDERUSE OF CHRONIC ORAL ANTI-COAGULATION IN ATRIAL FIBRILLATION (Abstract): The effectiveness of chronic oral anticoagulation in preventing thromboembolic events related to atrial fibrillation has already been proven. Nevertheless, a suboptimal use of oral anticoagulants is documented in real-world practice. **Aim:** To characterize individuals diagnosed with atrial fibrillation in need of chronic oral anticoagulation for thromboembolic prophylactic purposes, focusing on primary reasons of inadequate anticoagulation (lack of recommendation from the attending physician, inappropriate dosing and/or presence of contraindications). **Material and methods:** Patients presenting atrial fibrillation on admission or having been previously diagnosed with at least one episode of atrial fibrillation were included. Parameters like the type of atrial fibrillation (newly diagnosed, paroxysmal, persistent, permanent), associated thromboembolic and bleeding risk factors, as well as the long-term use of oral anticoagulants were assessed. **Results:** The study group comprised 90 subjects (mean age 75.83 ± 8.75 years, 40% men). All patients associated high thromboembolic risk according to CHA_2DS_2-VASC score. In one third of the patients no objective reason justifying the lack of anticoagulation was found. A reduced glomerular filtration rate (<60 mL/min/1.73 m^2) was noted in 34.4% of the study group. **Conclusions:** Our study confirmed the underuse of oral anticoagulants in patients with atrial fibrillation. If pathological conditions predisposing to high bleeding risk were excluded, the socioeconomic status represented the main argument when establishing the need for oral anticoagulation. Additional strategies to promote public awareness are needed in patients with atrial fibrillation requiring antithrombotic treatment. **Keywords:** ATRIAL FIBRILLATION, ORAL ANTI-COAGULATION, THROMBOEMBOLIC RISK, BLEEDING RISK.

The cardioembolic risk associated with atrial fibrillation represents a major healthcare concern. It has been estimated that among these patients the rate of developing thromboembolic events (ischemic stroke/transient ischemic attack/arterial embolism) ranges from 1 to 30% according to associated risk factors (1, 2). If the risk of stroke in patients with atrial fibrillation is estimated at 2.8% in persons aged 60 to 69 years, the risk increases to 23.5% in persons aged 80 to 89 years (3). Less clinically overt in short-term outcome, but equally disabling, conditions like cognitive

impairment and vascular dementia are more frequent associated with atrial fibrillation, having as a possible mechanism the formation of micro emboli and transient cerebral hypoperfusion (4).

As for any other prophylactic treatment, difficulties are encountered regarding patient's acceptance of a treatment not free of serious complications. The fear of bleeding complications associated with anticoagulants derives from the possible altered pharmacokinetics due to drug/food/alcohol interactions, low body mass index and altered body distribution of adipose tissue, polypragmasy, renal impairment, cognitive decline and balance disorders, which may increase the risk of falling (3, 5).

Despite a major worldwide interest in enhancing adherence to and acceptance of long-term oral anticoagulation in high-risk thromboembolic conditions, such as atrial fibrillation, current data sustain an underuse of chronic oral anticoagulation in up to 40-50% of the patients considered suitable candidates for anticoagulation (6, 7). Moreover, maintenance of anti-coagulants seems to raise as much difficulties as the decision to initiate the treatment. For instance, a therapy discontinuation rate of 30% was reported during the first year of treatment with vitamin K antagonists (VKAs), increasing to a rate up to 50% within the next two years (3, 8, 9).

MATERIAL AND METHODS

The study group is part of a larger group of patients evaluated during a four-year PhD research. Although the primary objective of the investigation was to assess the impact of several cardiac biomarkers in various types of heart failure, the study design and results being described in detail elsewhere (10), concomitant data revealed the underuse of oral anticoagulants in patients with atrial fibrillation. Hence, we conducted a subgroup analysis of a prospective observational study involving patients with atrial fibrillation aiming to perform a descriptive analysis of the reasons explaining the decreased rate of oral anticoagulation in clinical practice.

The study group included patients presenting to the 2nd Internal Medicine Clinic of the Iasi "Sf. Spiridon" County Clinical Emergency Hospital, diagnosed with atrial fibrillation on admission or who had been previously diagnosed with at least one episode of atrial fibrillation. The patients with valvular atrial fibrillation (prosthetic heart valves) were excluded from the study, due to differences in the management of anticoagulation therapy (higher VKAs doses are required corresponding to a higher bleeding risk; discontinuation of chronic anticoagulation involves an increased risk of mortality due to prosthetic valve thrombosis) (11).

According to the 2016 ESC Guidelines for the management of atrial fibrillation developed in collaboration with EACTS, atrial fibrillation was defined as: newly diagnosed (first diagnosed, irrespective of the duration of the arrhythmia), paroxysmal (self-terminated, in most cases within 48 hours, but some episodes may continue up to 7 days), persistent (lasts longer than 7 days) and permanent (accepted by the patient and physician, no rhythm control interventions required) (12).

The eligibility for anticoagulation was established according to the presence of high thromboembolic risk factors, assessed by the CHA_2DS_2-VASC score. Age $\geq$ 75 years and prior embolic events (stroke, transient ischemic attack, or thromboembolism) were assigned 2 points each, and

factors like congestive heart failure, hypertension, diabetes, vascular disease, age 65-74 years, and sex (female) were assigned 1 point each. A CHA_2DS_2-VASC score of 1 or more for men and 2 or more for women indicates the necessity to anticoagulated the patient (12).

Long-term use of chronic oral anticoagulants, dosage and type of anticoagulants were recorded (vitamin K antagonist – acenocoumarol or direct-acting oral anticoagulants (DOACs) – apixaban, dabigatran, rivaroxaban). For the group of patients treated with acenocoumarol, INR (International Normalized Ratio) level was determined in serum samples in order to evaluate the effectiveness of the treatment with vitamin K antagonists. The therapeutic INR range was considered 2.0-3.0.

The bleeding risk was assessed using the HAS BLED score, which includes parameters like associated hypertension, abnormal renal/liver function (1 point each), stroke, bleeding history or predisposition, labile INR, elderly people (≥ 65 years), drugs/alcohol concomitantly (1 point each). A HAS BLED score ≥ 3 indicates an increased risk of developing the hemorrhagic complications of anticoagulant treatment (12).

The study design was approved by the Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy Iasi and the Ethics Committee of the "Sf. Spiridon" County Clinical Emergency Hospital. from Iasi. All participants were informed about the study protocol and signed the informed consent.

Data were expressed as means ± standard deviations (SD) or medians and interquartile ranges (IQR), whichever was appropriate.

RESULTS

Our study included 90 patients. The mean age was 75.83 ± 8.75 years (IQR, 51-92 years), and there was a female predominance (60% versus 40% male patients). Most of the patients (53.33%) were in the 60-79 years age range. The mean glomerular filtration rate was 88.5 ± 38.89 ml/min/1.73m^2.

The distribution of patients according to the type of atrial fibrillation revealed the preponderance of permanent atrial fibrillation subgroup (fig. 1).

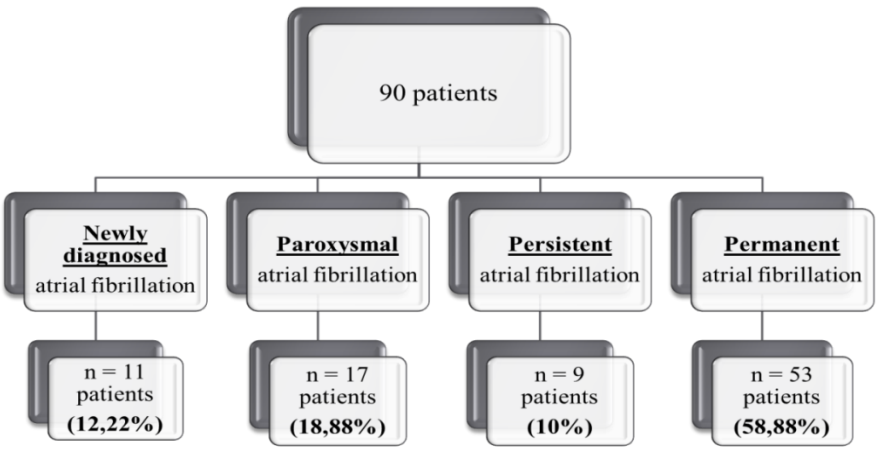

Fig. 1. Distribution of patients according to the type of atrial fibrillation

All patients associated high thrombo-embolic risk according to CHA_2DS_2-VASC score. The median CHA_2DS_2-VASC score was 5 (IQR 2-8) and the median HAS BLED score was 2 (IQR 1-6). A low prevalence of anticoagulant use was found, even in the presence of multiple embolic risk factors (fig. 2).

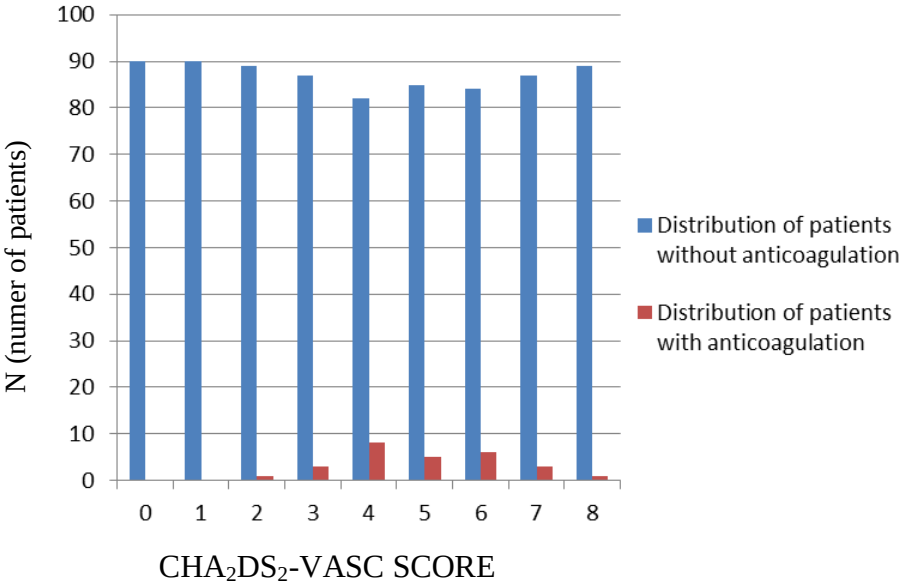

Fig. 2. Distribution of patients receiving chronic oral anticoagulation according to the CHA_2DS_2-VASC score (at admission)

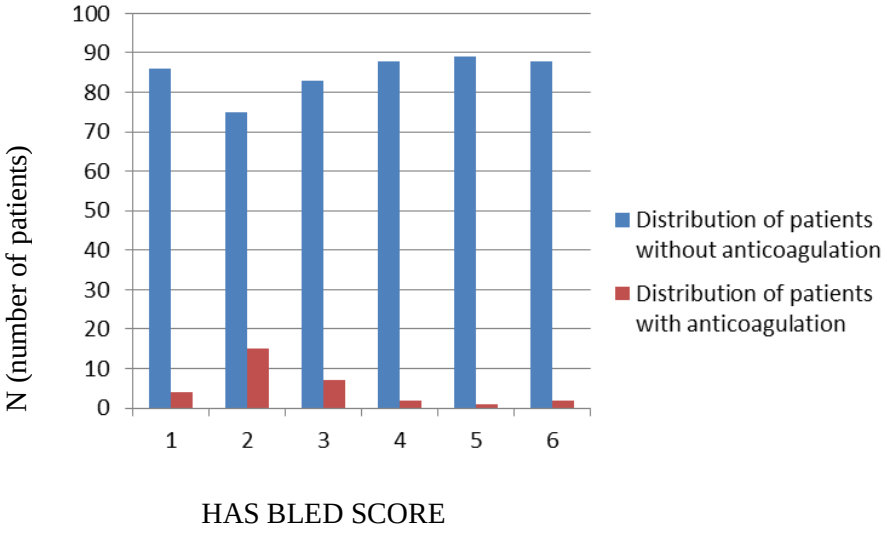

Fig. 3. Distribution of patients receiving chronic oral anticoagulation according to the HAS BLED score (at admission)

We identified 32.21% of the patients who were receiving anticoagulation treatment on admission, principally with acenocoumarol (fig. 3). The most relevant bleeding risk factors included age over 80 years (41.12%), alcohol abuse (22.22%), single or dual antiplatelet therapy (16.66%) or acenocoumarol overdose (6.66%). A reduced glomerular filtration rate (< 60 mL/min/1.73m^2) was recorded in 34.4% of the study patients.

Only 12.21% of the total number of patients (3.33% – therapeutic INR; 8.88% – DOACs) was properly anticoagulated. Nearly all patients treated with VKAs (acenocoumarol) had an INR level out of the therapeutic range, with the distribution of values shifted towards lower INR. No objective reason justifying the lack of anticoagulation was found in one third of the patients (35.56%) (tab. I).

DISCUSSION

We present a study involving patients with atrial fibrillation, high thromboembolic risk and inadequate anticoagulation. Irrespective of numerous studies that emphasize the importance of therapeutic anticoagulation, multiple physician-related factors and patient-related factors cause interferences with guideline-recommended antithrombotic treatment (2-7).

It is well stated that the benefits of chronic oral anticoagulation in atrial fibrillation are higher precisely for the groups of patients who associate higher bleeding risks, mainly elderly people (3, 13). Thus, the decision to anticoagulate a patient often requires "a leap of faith" from the attending physician who has to predict possible complications and maximize safety of antithrombotic treatment. Balancing the risk of developing ischemic stroke against the bleeding risk requires to evaluate the CHA_2DS_2-VASC and the HAS BLED scores.

In our study, all patients associated an increased risk of embolic events according

to the CHA_2DS_2-VASC score, thus requiring a long-term administration of oral anticoagulants. A significant percentage of patients had subtherapeutic acenocoumarol anticoagulation (INR < 2).

The results of this research agree with the reported data, the majority of the patients included lacking the antithrombotic protection. Similar results, at a much larger scale, were reported by Xian Y *et al.* (14) in a study involving 94,474 patients with atrial fibrillation and acute ischemic stroke. 83.6% of those patients were not receiving therapeutic anticoagulation.

The main reasons associated with no anticoagulation were represented by an advanced age (> 80 years), increased risk of trauma and associated hemorrhages. Poor adherence to oral anticoagulants and a significant variability in INR ranges have been found to be related to chronic alcohol consumption and social conditions. Furthermore, the socio-economic status of patient had a major impact regarding financial limitations when in need to buy direct-acting anticoagulants. The difficult access to health services, clinical laboratory or general practitioner contributed to a suboptimal INR surveillance.

After proper identification and correction, when possible, of factors that reduced compliance, the rate of oral anticoagulation at discharge increased to 75.54% (VKAs – 27.77%; DOACs – 47.77%) (tab. I).

Our study has limitations which have to be pointed out. As stated previously, we conducted a subgroup analysis of a larger research that, according to the initial study design, included patients with heart failure, irrespective of the presence or absence of atrial fibrillation. Thus, only a limited number of patients with atrial fibrillation were suitable for the current study. Further research is needed to proper analyze larger groups of patients and to consider the results representative for the North-East Region of Romania.

CONCLUSIONS

Our results confirm the underuse of oral anticoagulants in patients with atrial fibrillation. If pathological conditions predisposing to high bleeding risk are excluded, the socioeconomic criteria represent the main argument when establishing the need for oral anticoagulation. Additional strategies to promote public awareness are necessary in patients with atrial fibrillation requiring antithrombotic treatment. Identifying potentially modifiable bleeding risk factors is of major interest in order to optimize the rates of oral anticoagulation for atrial fibrillation.

It is also important to underline in medical practice the no utility place for antiplatelets in atrial fibrillation patients, adding no benefit but higher hemorrhagic risk. Further dissemination of ESC and EHRA guidelines among practitioners is mandatory.

NEWS

SHOULD WE USE DENTAL IMPLANTS EVERY TIME?

Nowadays, dental implants have become more common treatment for replacing missing teeth and aim to improve chewing efficiency, physical health, and esthetics. Although the survival rate of dental implants over a 10-year observation has been reported to be higher than 90% in totally edentulous jaws, the clinical outcome of implant treatment is challenged in compromised (bone) conditions, as are frequently present in elderly people. The biomechanical characteristics of bone in aged patients do not offer proper stability to implants, being similar to type-IV bone (Lekholm & Zarb classification), in which a decreased clinical fixation of implants has been clearly demonstrated. However, the search for improved osseointegration has continued forward for the new evolution of modern dental implants. This represents a continuum of developments spanning more than 20 years of research on implant related-factors including surgical techniques, implant design, and surface properties **(**Hamdan S. Alghamdi. Methods to Improve Osseointegration of Dental Implants in Low Quality (Type-IV) Bone: an Overviewhttp://dx.doi.org/ 10.3390/jfb9010007).

COXITIS REHABILITATION TREATMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS (Abstract): The study aims to assess and compare the efficiency of two different kinetic programmes, in order to improve the treatment of patients with ankylosing spondylitis (AS). **Material and method**: Our study included two samples (control and cases) of 30 patients admitted for AS and unilateral coxitis in the Clinic of Rheumatology and Medical Rehabilitation Iasi, between 2008-2009. Certain paramentres such as: age, body mass index, disease evolution, Schober test, index-earth test, inspir-expir index, BASDAI activity index, BASFI functional index, Health Assessment Questionaire (HAQ), pain, morning ankylosing inflammatory tests, and general state of health were assessed at every patient. **Results**: No variation with statistical significance were registered between the two samples. The Pilates method used in the rehabilitation treatment of patients with AS could have a favourable effect on indices regarding mobility, as well as patients' perception about their disease. **Key words**: ANKYLOSING SPONDYLITIS, PILATES METHOD, REHABILITATION

Spondilita anchilozantă este o boală inflamatorie cronică, care vizează în principal scheletul axial, dar şi articulaţiile periferice, caracteristica majoră fiind afectarea precoce a articulaţiilor sacroiliace. Face parte din grupul spondilartropatiilor seronegative, ca entitate reprezentativă a spondilartritelor axiale. Prevalenţa spondilartritelor în populaţia generală a fost raportată a atinge 1,9% (1 2,3,4).

Fiind o boală cu caracter evolutiv şi cu un înalt grad de invaliditate, momentul începerii kinetoterapiei trebuie să fie cât mai precoce (5,6,7). Principiul de bază este încercarea de a preveni sau limita anchilozele şi devierea coloanei şi/sau a articulaţiilor centurilor, predominând programul de kinetoprofilaxie primară şi secundară şi, în mai mică măsură, cel kineto-terapeutic sau de recuperare (8,9,10).

Studiul de faţă îşi propune a evalua şi compara eficienţa a două programe kinetice diferite, în scopul eficientizării şi modernizării tratamentului kinetic la pacienţii cu spondilită anchilozantă.

MATERIAL ŞI METODĂ

În studiu au fost incluşi 30 pacienţi cu diagnosticul de spondilită anchilozantă şi coxită unilaterală, internaţi în Clinica de Reumatologie şi Recuperare Medicală din cadrul Spitalului de Recuperare Iaşi, în perioada 2008-2009.

Urmărind a evalua beneficiile unui nou

program de kinetoterapie, am exclus din studiu pacienţii în stadii avansate de boală, pe cei cu alte afecţiuni articulare, cu patologii care contraindicau efortul fizic susţinut, cu obezitate, pe cei care aveau deja un program kinetic la domiciliu, precum şi pe cei aflaţi sub terapie biologică. Ne-am referit doar la pacienţii în stadii incipiente, când recuperarea poate fi eficientă în a preveni degradarea staticii şi dinamicii.

Cu ajutorul unei fişe de anchetă clinico-epidemiologică, special concepută, au fost urmăriţi, pentru fiecare pacient în parte, principalii parametri clinici şi paraclinici, la internare şi la 10 zile. Pacienţii au fost împărţiţi în două loturi egale numeric şi randomizaţi, astfel încât loturile să fie asemănătoare.

REZULTATE ŞI DISCUŢII

Parametrii luaţi în studiu şi evaluaţi la fiecare pacient au fost: vârsta, indicele de masă corporală (IMC), durata de evoluţie a bolii, rezultatele testului Schober, indicele index-sol, indicele inspir-expir, indicele de activitate a bolii BASDAI, indicele funcţional BASFI, indicatorul de calitate a vieţii HAQ, redoarea matinală, oboseala, durerea, testele de inflamaţie şi starea generală de sănătate evaluată de către medic şi de către pacient. Nu au fost înregistrate variaţii cu semnificaţie statistică între cele două loturi (tab. I).

Pentru evaluarea articulaţiei coxofemurale afectate, a fost luată în consideraţie toată gama de mişcări, notându-se valorile goniometrice pentru fiecare tip în parte (tab. II).

Pentru toţi pacienţii internaţi, tratamentul aplicat a respectat principiile terapeutice clasice: programul educaţional şi igieno-dietetic, tratamentul medicamentos, fizic, masaj şi hidroterapie.

Cele două loturi au practicat exerciţiile clasice în aceeaşi măsură, câte 30 minute/zi. Pacienţii din lotul cu *Pilates* au mai efectuat un program de 30 minute la distanţă de 5 ore de primul, care a conţinut exerciţii pentru ameliorarea posturii, tonifierea musculaturii, creşterea amplitudinii de mişcare şi ameliorarea respiraţiei.

Întregul concept al *metodei Pilates* se bazează pe convingerea că, fortifiind această regiune anatomică, se optimizează capacităţile individuale de funcţionare în activităţile zilnice. Pilates denumeşte această regiune "powerhouse", ceea ce sugerează că aceasta

TABELUL II

Evaluarea diverselor tipuri de mişcări la pacienţii cu spondilită anchilozantă, incluşi în studiu

Mişcări	Lot martor	Lot Pilates	p
Flexie	35,5±1,2	34,9±2,1	NS
Extensie	10,3±2,3	11,2±1,5	NS
Abducţie	25,5±1,6	26,1±2,1	NS
Adducţie	15,3±1,7	15,9±2,3	NS
Rotaţie internă	26,7±1,3	25,9±1,4	NS
Rotaţie externă	15,5±2,4	14,8±2,6	NS

este regiunea generatoare şi o delimitează între planşeul pelvin şi cutia toracică.

Reevaluarea s-a făcut la 10 zile după începerea tratamentului. Mobilitatea axială s-a îmbunătăţit în ambele loturi, mai mult în lotul care a efectuat metoda *Pilates*, acest fapt constatându-se din reevaluarea indicelui Schober şi a indicelui index-sol, care, deşi fără semnificaţie statistică deosebită, este totuşi de notat, având în vedere caracterul anchilozant al bolii (tab. III).

În privinţa indicatorului BASDAI şi indicelui BASFI, am înregistrat de asemenea o ameliorare uşoară comparativ cu lotul martor, fapt cu o importanţă deosebită pentru prognosticul evolutiv al bolii. O îmbunătăţire a oricăruia dintre aspectele la care se referă întrebările chestionarelor mai sus menţionate se asociază cu îmbunătăţirea calităţii vieţii.

În privinţa evaluării calităţii vieţii, am utilizat chestionarul HAQ (Health Assessment Questionaire), adaptat pentru pacienţii cu spondilită anchilozantă, pentru aprecierea cât mai exactă a calităţii vieţii acestora. Scorul final al scalei variază între 0 şi 3 (tab. IV).

În privinţa mişcărilor efectuate din articulaţia coxo-femurală afectată, trebuie subliniată ameliorarea îmbucurătoare a mobilităţii, pe toate planurile de mişcare, mai crescută în lotul supus metodei Pilates (tab. V).

Indicele de calitate a vieţii HAQ a avut valori net favorabile în lotul care a aplicat metoda *Pilates*, stabilindu-se o corelaţie cu semnificaţie statistică. Rezultatele implică o complianţă bună a pacienţilor la noua metodă implementată şi impactul semnificativ asupra modului în care aceştia percep afecţiunea de care suferă. Acest lucru s-ar putea datora faptului că pacienţii care au efectuat exerciţii preluate din metoda *Pilates* au fost

încurajaţi în continuu să se implice şi să perceapă progresele pe care le reuşesc pe durata tratamentului.

Markerii de inflamaţie repetaţi la externare s-au îmbunătăţit la majoritatea pacienţilor din ambele loturi, la fel ca şi ceilalţi parametri evaluaţi.

CONCLUZII

Kinetoterapia este esenţială la pacientul cu spondilită anchilozantă; dacă tratamentul medicamentos este absolut necesar, menţinerea funcţionalităţii şi reeducarea funcţională a articulaţiilor interesate are o importanţă fundamentală pentru prevenirea, întârzierea şi corijarea deformărilor articulare, de postură şi ale aliniamentului.

Includerea metodei *Pilates* în tratamentul recuperator al pacienţilor cu spondilită anchilozantă poate avea un efect favorabil asupra atât a indicatorilor obiectivi privind mobilitatea, cât şi a percepţiei pacienţilor despre afecţiunea de care suferă.

Deşi medicaţia contribuie la menţinerea/refacerea amplitudinii de mişcare prin absenţa durerii şi controlul procesului inflamator, metodele şi tehnicile kinetice sunt cele care asigură funcţionalitatea optimă, corectă a segmentelor corpului la pacientul cu spondilită anchilozantă.

NEW INSIGHTS INTO DIAGNOSIS AND THERAPEUTIC MODULATION OF DRUG-INDUCED HEPATOTOXICITY (Abstract): Drug-induced hepatotoxicity may be the consequence of numerous drugs and chemical compounds, such as antimicrobial agents, anticonvulsant drugs, antineoplastic medication, herbal medicines and dietary supplements. The early and correct diagnosis of the drug-induced liver injury is an important aspect that allows for adequate therapy and the possibility of assessing the severity and prognosis of this pathological condition. Currently, the variations of serum transaminase, alkaline phosphatase and total bilirubin values, represent usual, but suboptimal laboratory parameters for the identification of presence, severity and the evolution of liver damage. Some biomarkers such as: apoptotic index, glutamate dehydrogenase, high mobility group box 1 protein and microRNA-122, are recently considered the valuable candidates in assessing the drug induced liver injury. A lot of active substances: chitosan, quercetin, collagen, citral, have been extensively investigated and proved hepatoprotective, antioxidant and anti-inflammatory effects during the *in vitro* and *in vivo* researches. The use of different compounds based on biocompatible polymers and natural substances represents a generous research direction and provides interesting perspective on development of innovative hepatoprotective agents. **Keywords:** DRUG-INDUCED HEPATOTOXICITY, DIAGNOSIS, BIOMARKERS, HEPATOPROTECTIVE, ANTIOXIDANT.

The purpose of this review is to reveal the classic and modern diagnosing possibilities, and the therapeutic opportunities to modulate the evolution of drug-induced hepatotoxicity. A great variety of chemicals (drugs, recreational agents, ethyl alcohol, toxic compounds, industrial and domestic substances, herbal medicines and dietary supplements) is an important cause of hepatocytes alteration, the majority being responsible for different degree of liver injury (1).

Drug-induced liver toxicity

Drug-induced hepatotoxicity is a frequent cause of hepatic damage, with a wide range of manifestations, the most severe of which is hepatocellular death, leading to

acute hepatic failure (2). Risk factors include idiosyncrasy, age, gender, alcohol consumption, concomitant use of other drugs, pre-existing liver disease, obesity, genetic and environmental factors (3, 4). The liver plays an important role in the biotransformation of drugs or exogenous toxic substances. Pathological status of the liver may disturb the metabolism of various chemical agents, thus affecting the efficacy and the development of adverse reactions, while some their metabolites may directly cause hepatic injury. Drug-induced hepatotoxicity may be determined by the administration of numerous and various drugs and chemical substances such as antimicrobial chemotherapeutic medication, anticonvulsants, antineoplastic drugs, herbal remedies and dietary supplements (5, 6).

There are two main forms of hepatotoxicity: intrinsic and idiosyncratic (7). Hepatic damage may be the result of direct toxicity from the administered drug, one of its metabolites, or the lesion may be due to immune-mediated mechanisms (8).

Basic diagnosis
of drug-induced liver toxicity

Hepatic lesions can be classified into hepatocellular, cholestatic and mixed, being caused by increasing in alanine aminotransferase and alkaline phosphatase concentrations, above the upper limit of normal (9). Serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST), alkaline phosphatase levels and total bilirubin, although not specific for drug-induced liver damage, remain the parameters for the detection and classification of liver lesions. However, serum ALT cannot differentiate drug-induced hepatic cytolysis from necrosis of other causes, such as viral hepatitis. In addition, important elevation of serum ALT may even occur in other cases of hepatic damage due to, for example, the liver accumulation of glycogen in poorly controlled diabetes mellitus; in autophagy of hepatocytes in the context of anorexia nervosa and, also, in hepatic steatosis (10).

In addition, frequent and high increase of ALT, can often be caused by drugs that have little potential, or do not cause clinically important liver damage, such as statins, but it is unclear, whether this increased enzyme activity, really reflects the existence of hepatic lesions. In other situations (such as isoniazid, troglitazone, ximelagatran use), it is possible to occur hepatocyte lesions, including necrosis, but elevated serum ALT levels decrease over time, after continuing treatment, as a result of a so-called adaptive process (11). It appears that, this adaptive adjustment involves altering the regulation of production the metabolic enzymes of drugs and transporters. Changes in the regulation of transporters, have been observed in the human liver during recovery of drug-induced hepatopathy, suggesting that similar adaptive mechanisms may be operative in both rodents and humans. A widely accepted theory is that, patients developing clinically manifested drug-induced hepatotoxicity are a group of people with increased ALT values that cannot adapt to existing lesions (10).

Data from the literature shows that a concomitant increase in serum ALT and bilirubin is a much better predictor of evolution, indicating severe liver damage during a hepatocellular lesion, than the increase in ALT alone. It is considered, however, that bilirubin together with ALT, are not optimal assessment parameters, because during hepatic impairment there must be a very large destruction of functional hepato-

cytes before bilirubin increases. However, the simultaneous existence of elevated levels of these two parameters signifies an increased risk in liver failure (11).

For proper management of idiosyncratic hepatotoxicity, one of the key questions is whether, in a patient with this reaction, it will progress to a serious liver lesion with potentially fatal outcome or will be spontaneously remitted, after discontinuation of the causative agent. A diagnostic algorithm that allows the identification of risk factors and the prediction of subsequent clinical development, will greatly facilitate the appropriate treatment of acute liver injury. The current lack of testing the predictive safety, prior to the administration of a potentially hepatotoxic compound, reinforces the need for rapid identification of a high-risk hepatotoxicity situation, involving additional monitoring (10).

There is a growing need for *in vitro* researches, to predict the risk of drug-induced hepatotoxicity, before initiating studies in human subjects. Such investigations are based on human-derived cell culture studies, to evaluate mitochondrial toxicity, inhibition of transporters, induction of oxidative stress and others involved in pathophysiological mechanisms (11).

Biomarkers in the evaluation of drug-induced liver toxicity

A number of new biomarkers are, currently, being considered, for systematic implementation in future studies, related to drug-induced hepatotoxicity investigation (12). The researches performed in rodent, indicate that the ratio between the caspase fragment of cytokeratin 18 and total serum K18 (called the "apoptotic index"), estimates the relative level of apoptosis, compared to necrosis, during drug-induced liver lesions.

Glutamate dehydrogenase can specifically differentiate the damage of the liver, from the muscular damage, additional highlighting mitochondrial toxicity, as a mechanism of hepatic impairment. It is known that microRNA-122 is a liver specific marker, however, recent data suggesting it may be actively released from the hepatocytes, in the absence of visible toxicity, which reduces the enthusiasm for considering it to be specific for drug-induced hepatotoxicity (13, 14).

Finally, a number of specific molecular structures, associated with liver damage, especially the high mobility box 1 nuclear protein and its various modified forms, are promising biomarkers of innate immune activation, useful to distinguish the so-called benign increasing of aminotransferase, over those that indicate clinically important liver lesions (7). Recently, these new biomarkers are used in early clinical trials, but widespread acceptance of their use, will require extensive in-depth studies.

Therapeutic promises valuable in drug-induced hepatotoxicity

Literature data highlight the fact that a number of natural compounds (of vegetable or animal origin) or some polymers have hepatoprotective effects on lesions induced by medication or toxic agents, antioxidant and anti-inflammatory actions (15, 16, 17).

One of the modern medicine challenges is the use of nanotechnology to optimize pharmaceutical forms of drugs, in order to limit their liver toxicity. The important technological advantages of nanoparticles used as drug delivery systems, are represented by the targeted release of active substance, prolongation of drug action in the target tissue and lowering their adverse

effects.

Various biocompatible and biodegradable polymers, or some natural compounds, have given rise to a great interest from numerous researchers to investigate their potential as drug carriers with possible biomedical applications (18).

Chitosan, a marine polysaccharide made from crustaceans, has long attracted attention, especially as a biocompatible material, due to its anti-tumor, anti-ulcer, immunostimulatory, antioxidant and antibacterial activities. Experimental studies have shown that chitosan exhibits hepatoprotective effects due to the improvement of endogenous antioxidant defense systems and the reduction of lipid peroxidation in the experimental model of acetaminophen-induced hepatotoxicity in rats (19). The use of original nanoparticles based on chitosan proved to have potent antioxidant, anti-hyperlipidemic actions and hepatocytes protective effects on alcohol and fatty regimen (20). Isoniazid and rifampicin both induced (21) experimental hepatotoxicity in rats.

Other pharmacological active agent, the polyphenolic flavonoid compound quercetin, known to possess effective antioxidant, anti-inflammatory properties and a protective activity in different pathological states, evidenced potent effects in prevention of hepatic injuries in both acetaminophen and acrylamide-induced liver toxicity in rats (22, 23). The treatment with nano-formulations based on quercetin showed hepatoprotective and antioxidant influence, against liver cytotoxic injuries induced by aflatoxin B1 in rats, as well as *in vitro* studies performed on hepatocytes cultures (24). Moreover, the association of the flavonoid agent quercetin, demonstrated dose-dependently potentiation of chitosan actions, to improve the biochemical parameters and histological liver architecture, in rats with experimental-induced hepatotoxicity with carbon tetrachloride (25).

Literature data suggests that some types of collagen, such as marine origin (extracted from the skin of some salmon species), have various biological functions, including antihypertensive, anti-ulcer, anti-aging, but also liver protective activities. The antioxidant and hepatoprotective effects of marine collagen, have been confirmed by diminishing the activity of oxidative stress markers, decreasing in serum levels of aminotransferases, improving the lipid profile, reducing the hepatic histological lesions in rats with toxic alcoholic hepatopathy (26). Other researches highlighted hepatoprotective influences of collagen peptides obtained from some fish species skin, demonstrated by reduction in serum liver enzymes level, the intensification in antioxidant enzymes activity in rats with drug-induced liver damages. Additionally, the *in vitro* studies showed a substantial increase in hepatocytes viability in the culture cells pre-treated with these cod skin collagen peptides (27).

It is known that, the monoterpene citrate, an essential oil, the component of lemongrass oriental plant, has many biological effects, such as antibacterial and anti-inflammatory. The researches also demonstrated the citrate significant antioxidant activity, anti-inflammatory effects and hepatoprotective actions on experimentally acetaminophen-induced hepatopathy in mice (objected by decreasing the aminotransferases activity and by improving of liver histopathological lesions) (28, 29).

Other interesting research direction, is using diazeniumdiolate derivatives O(2)-vinyl 1-(pyrrolidin-1-yl)diazen-1-ium-1,2-

diolate (V-PYRRO/NO) or O2-vinyl-[2-(carboxylato)pyrrolidin-1-yl]diazen-1-ium-1,2-diolate (V-PROLI/NO), nitric oxide donors, which proved hepatoprotective effects in different experimental models of liver damage, represented by acetaminophen-induced hepatotoxicity, D-glactosamine/endotoxin-induced liver injury and nonalcoholic fatty liver disease in rodents (30, 31).

CONCLUSIONS

Our study revealed that drug-induced hepatotoxicity is the most common cause of liver injury in the clinical practice. Currently, the variations of serum transaminase, alkaline phosphatase and total bilirubin values represent the usual, but suboptimal laboratory parameters for the identification of the presence, severity and the evolution of liver damage. Some biomarkers, such as apoptotic index, glutamate dehydrogenase, high mobility group box 1 protein and microRNA-122, are recently used in assessing the drug-induced liver injury.

The use of different compounds based on biocompatible polymers and natural substances represents a generous research direction and provides interesting perspective on development of innovative hepatoprotective agents.

CLINIC AND BIOLOGIC CORRELATIONS CONCERNING ESOPHAGEAL VARICES IN PATIENTS WITH COMPENSATED HEPATIC CIRRHOSIS (Abstract): **Material and methods**: The retrospective study included 126 patients with hepatic cirrhosis (HC) CHILD A class, assisted in Botoşani Hospital, during 2007 and 2008. Patients were clinic, biochemical, hematological, etiological, ultrasonographic, endoscopical examined. Statistical analysis carried out with EXCEL soft and SPSS 16.0 soft, calculating chi^2, p, ROC curve, SPRI and ASPRI values. **Results**: We assessed the sample characteristics using the univariate analysis: age, the presence / absence of esophageal varices, SPRI score (limit value ≥ 15.5), ASPRI score (limit value ≥ 19.3). **Conclusions**: Non-invasive prediction cannot exclude the endoscopic exam in patients with compensated HC, caused especially by the virus C and alcohol consumption. Thrombocytopenia and splenomegaly and Fibroscan exam were the best non-invasive indicators to predict the esophageal varices. **Key words**: ESOPHAGEAL VARICES, NON-INVASIVE PREDICTORS, LIVER CIRRHOSIS, ENDOSCOPIC SCREENING

Formarea, dilatarea şi în final ruperea varicelor esofagiene (VE) reprezintă o complicaţie majoră, dramatică a hipertensiunii portale (HTP) din ciroza hepatică. Posibilitatea de a identifica prin metode non-invazive prezenţa VE este utilă pentru a selecta pacienţii care necesită screening endoscopic (1,2,3). Cu ocazia primului diagnostic, VE sunt prezente la aproximativ 40% din pacienţii cu ciroză hepatică (CH) compensată şi la 60% din cei decompensaţi, cu ascită. La pacienţii fără VE, rata de apariţie a acestora este de 5-10 % pe an şi cu tendinţa de a progresa spre cele de gradul I şi II şi apoi la III şi IV, cu riscul de sângerare (4,5). În prezent, se recomandă evaluarea endoscopică a pacienţilor cu CH, cu includerea acestora în programe preventionale, pentru a reduce riscul sângerării varicelor. O asemenea orientare implica existenţa unor echipamente şi aparatură medicală de înaltă performanţă, cu costuri ridicate. În acest context, a crescut interesul pentru intervenţiile non-invazive, clinice, biologice, imagistice care au putere de predicţie pentru prezenţa VE (6,7,8,9).

Studiul nostru urmăreşte determinarea parametrilor clinici, biologici şi ecografici cu valoare în orientarea diagnostică a prezenţei VE în CH şi aplicabilitatea lor în practica medicală curentă.

TABELUL I
Calcularea indicilor ASPRI, SPRI

Indicator	Calcul
SPRI	Diametrul longitudinal al splinei (cm) / numărul de trombocite (10^6 / ml) x 100
ASPRI	Vârsta (ani): < 30 = 0; 30-39 = 1; 40-49 = 2; 50-59 = 3; 60-69 = 4; ?70 = 5
	ASPRI = vârsta + SPRI

MATERIAL ŞI METODE

Studiul retrospectiv a inclus 126 pacienţi cu CH clasa CHILD A, internaţi în compartimentul de gastroenterologie al Spitalului Judeţean „Mavromati", Botoşani, în perioada 1.01.2007 - 31.12.2008 şi care au fost urmăriţi la intervale de 6 săptămâni, 6 luni şi 1 an. Pacienţii au fost examinaţi clinic complet, concomitent cu efectuarea bilanţului biochimic, hematologic, evaluarea etiologică, examinarea ecografică abdominală cu înregistrarea diametrului longitudinal al splinei. Lotul de studiu a fost evaluat, iniţial, prin endoscopie digestivă superioară cu notarea prezenţei VE, varicelor gastrice şi gastropatiei portale. S-a calculat scorul de gravitate CHILD POUGH selectându-se pacienţii din clasa A. Diagnosticul de CH a fost susţinut de elementele clinice, biochimice şi ecografice. Au fost excluşi pacienţii care au prezentat : sângerare a varicelor în antecedente, tromboză venoasă portală evidenţiată ecografic, alte cauze de splenomegalie, precum şi cei aflaţi în tratament cu antagonişti ai receptorilor beta-adrenergici. ASPRI şi SPRI s-au calculat după formula derivată din combinarea valorilor de vârstă, mărimea splinei şi valoarea trombocitelor (tab. I).

Analiza statistică s-a efectuat cu ajutorul programelor Microsoft Excel si un soft SPSS versiunea 16.0, şi indicatori statistico-matematici uzuali (chi^2, p, curba ROC, valorile prag pentru SPRO şi ASPRI).

REZULTATE ŞI DISCUŢII

1. Caracteristicile lotului de studiu. Cei 126 de pacienţi au avut vârsta medie de 52 (19-85 ani). La endoscopie, VE digestivă

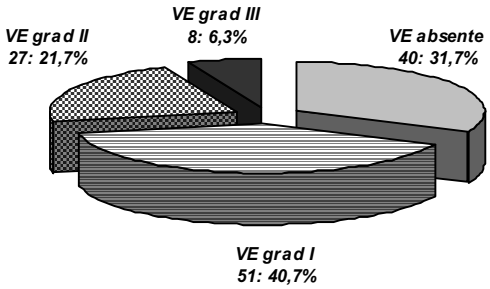

Fig. 1 . Repartiţia varicelor esofagiene

superioară a fost prezentă la 99 (78,5%) – 40,7% gr. I, 21,7% gr. II şi 6,3% III) (fig. 1).

2. Analiza univariată a evidenţiat relaţia prezenţei sau absenţei VE cu diverşi parametri (tab. II). Prin analiza univariată, 6 parametri au fost găsiţi cu semnificaţie statistică pentru : vârstă, trombocitopenie, splenomegalie, prezenţa circulaţiei colaterale abdominale, scorurile SPRI şi ASPRI. Compararea grupurilor definite de prezenţa sau absenţa VE s-a realizat utilizând teste statistice specifice (tab. III).

3. Evaluări statistice. Reprezentarea în diagrame boxplot a repartiţiilor celor doua grupuri (prezenţa şi / sau absenţa VE) în legătura cu valorile trombocitelor, valoarea SPRI şi valoarea ASPRI este ilustrată în figura 2, diagramele 1, 2, 3. S-a constatat că 92,9 % din cazurile cu trombocitopenie medie sau severă au prezente VE. Rezultatele obţinute în urma estimării modelului prin testul Hosmer-Lemeshow arată că *modelul este semnificativ statistic***,** cu o bună concordanţă a modelului cu datele analizate. Se poate spune că aproximativ 60,5% (Nagelkerke R Square) din varianţa iniţială este regăsită în model. Analiza clasificărilor predictive privind prezenţa şi absenţa VE, arată un procentaj global foarte bun al cla-

prag a SPRI ≥15,5, având puterea cea mai mare de predicţie pentru prezenţa VE (sensibilitate 67%, specificitate 66,7%); pentru *scorul ASPRI* o arie de 0,686 (cu p=0,003, interval de încredere 0,58-0,78) şi o valoare prag a ASPRI≥19,3, având puterea cea mai

TABELUL IV

Prognoza prezenţei / absenţei varicelor esofagiene în cadrul modelului

Valori observate		Valori prognozate de model		
		varice esofagiene		Clasare corectă (%)
		absente	prezente	
Varice esofagiene	absente	16	11	59,3
	prezente	7	88	92,6
Clasare corectă (%)				**85,2**

mare de predicţie pentru prezenţa VE (sensibilitate 64,9%, specificitate 63%).

Trombocitopenia este în relaţie inversă cu VE şi, din analiza valorilor, se poate fixa un prag de 98.000 mm^3 (sensibilitate 66%, specificitate 55%). Pentru *splenomegalie*, aria ROC are o valoare bună, de 0,655 (p= 0,014), cu o valoare prag de 150 mm, când obţinem sensibilitatea 65% şi specificitatea 55%.

Analiza ROC a scorurilor SPRI şi ASPRI diferenţiate după etiologia cirozei hepatice arată că, pentru lotul pacienţilor cu ciroză alcoolică, curba ROC nu este semnificativă şi valoarea prag pentru SPRI diferă la etiologia virală C (≥15,58, sensibilitate 71% şi specificitate 70%) faţă de etiologia virală B (≥17,1, sensibilitate 70%, specificitate 71,4%). Valoarea ASPRI este relativ similară la loturile cu etiologie VHB şi VHC. În mod surprinzător, aici s-a constatat că, pe lângă lotul de pacienţi cu ciroză alcoolică şi la cei cu ciroză VHB curba ROC are o semnificaţie la limită. Puterea de predicţie a indicatorilor ASPRI, SPRI, trombocite, splină este relativ similară dacă se compară ariile ROC.

CONCLUZII

Rezultatele de predicţie pentru VE obţinute sugerează că predicţia non-invazivă nu are o acurateţe suficientă pentru a elimina examenul endoscopic, la pacienţii cu CH compensată. S-a dovedit că grupul de vârstă 50-59 ani, cu prevalenţa cea mai ridicată în rândul lotului studiat şi, de asemenea, vârsta este factor independent de predicţie în analiza multivariată, atestând vechimea infecţiei cu virusul hepatitei C sau a consumului de alcool.

Trombocitele şi splina sunt parametri bine corelaţi cu prezenţa şi/sau absenţa VE, având semnificaţie statistică în analiza uni- şi multivariată, ei caracterizând relevant hipertensiunea portală din ciroza hepatică. Până în prezent, s-au dovedit cei mai buni indicatori non-invazivi în prognozarea prezenţei VE. Studiile efectuate în privinţa valorii scorurilor APRI şi ASPRI au rezultate divergente, posibil datorate diferenţelor de lot studiat.

Ca markeri non-invazivi, examenul Fibroscan are o acurateţe bună, dar şi limite de aplicabilitate pentru pacienţii obezi şi din cauza costurilor ridicate. Studiile în curs se preocupă de compararea performanţelor testelor non-invazive şi anume Fibroscan, Fibrotest şi ale raportului trombocite / diametrul splinei, în aprecierea prezenţei VE. Utilizarea markerilor non-invazivi poate ameliora raportul cost-eficienţă şi îmbunătăţi managementul medical al pacienţilor cu ciroză hepatică, prin limitarea examinării endoscopice la un subgrup de pacienţi consideraţi cu risc, dar, în prezent, Consensul Baveno IV, care recomandă screening-ul endoscopic ca fiind cea mai bună metodă pentru detectarea VE, la toţi pacienţii cirotici, rămâne neschimbat şi cu largă aplicare.

NOUTĂŢI

IDENTIFICAREA RAPIDĂ ŞI SIMPLĂ A RISCULUI DE MORTALITATE ÎN INSUFICIENŢA CARDIACĂ

Numeroase scoruri au fost imaginate pentru predicţia riscului de deces în insuficienţa cardiacă. În studiul EURO HEART SURVEY, care a inclus 10701 subiecţi cu insuficienţă cardiacă (IC) recrutaţi din 115 centre europene, un procent important de pacienţi, 1404 (13%) au decedat în primele 12 săptămâni de supraveghere. Într-o analiză univariabilă, vârsta, sexul feminin, un QRS lărgit pe electrocardiogramă, cât şi existenţa unei hiponatremii, hipokaliemii, insuficienţe renale, anemii, a unei insuficienţe mitrale severe, sau a unei insuficienţe ventriculare stângi severe au însoţit un prognostic rezervat. Tratamentul cu inhibitori ai enzimei de conversie (IEC), betablocante, derivaţi nitraţi, sau hipolipemiante au ameliorat prognosticul. Într-o analiză multivariabilă au rămas ca factori predictivi (odds ratio – OR < 1 fiind protectiv): vârsta (OR 1,5), insuficienţa ventriculară stângă severă (OR 1,8), creşterea cretininemiei (OR 1,2), natremiei (OR 0,9), hemoglobinei (OR 0,9). Pe plan terapeutic warfarina s-a dovedit a fi protectoare (OR 0,5), antiagregantele plachetare (OR 0,6), spre deosebire de heparină (OR 1,7) şi medicaţia inotropă (OR 5,5). Alte medicamente, precum IEC (OR 0,5), betablocante (OR 0,7), statine (OR 0,6) sau inhibitori calcici (OR 0,7) au ameliorat toate prognosticul. Este uşor de clasificat subiecţii în cohorte utilizând un scor simplu de risc permiţându-se astfel predicţia mortalităţii pe termen scurt. Acesta ar cuprinde: vârsta, nivelul de afectare al ventriculului stâng, tratamentul cu betablocante, IEC, nivelul creatininemiei. Se pare că este relativ uşor de a identifica rapid şi simplu pacienţii cu risc în cursul unei spitalizări pentru IC (Velavan P et al. Predictors of short term mortality in heart failure — Insights from the Euro Heart Failure survey. *Int J Cardiol* 2010; 138: 63–69).

POST COITAL ALLERGY-A CASE REPORT OF POST ORGASMIC ILLNESS SYNDROME (Abstract) The post-orgasmic illness syndrome (POIS) is a rare, but debilitating cluster of symptoms, occurring after ejaculation. The clinical case presented is a male patient, his complains started after ejaculation, four years ago, with flu-like symptoms, feverishness and sweating, brain fog, muscle pain and heavy legs, followed by concentration and attention difficulties and irritation. This status last for about 5 to 7 days, disappear spontaneously after 3 days and reappear after the next ejaculation. This postcoital illness was worsening during the years. The clinical assessment and differentiation of the diagnosis was difficult and consisted in several clinical criteria, a functional test and allergy valuation. The combination of symptoms and pathophysiological mechanisms pointed to other sex related allergies, such as seminal plasma protein allergy. **Keywords***:* SEMINAL PLASMA PROTEIN ALLERGY, POST ORGASMIC ILLNESS, SEXUAL DISTRESS.

The only universal in human sexuality is variability itself (1). During the last 5 years we have diagnosed and treated three different cases of sex allergy: latex allergy, seminal plasma allergy and, the most recent, post orgasmic illness syndrome (POIS). Sex and intimate contacts can represent a risk factor for allergic reactions, because they may favor direct contact with sensitizing substances(1).

Pathogenesis of POIS might include type 2 immune allergic reactions, but it does not necessary involve atopy (2). The mean serum total IgE in the non-atopic males was 27 kU/L (range 6-78 kU/L), indicating that in these men this immunological marker was normal (2).

Pathophysiology of POIS shows an immunological process which explains the systemic reaction of the body and not only a local genital reaction, since only the immune system is capable of inducing very rapid and serious physical and mental symptoms (3). The support for an immunological cause of these flu-like complaints was found in reports on cytokines inducing a flu-like state (4, 5). There are two types of POIS, a primary type in which POIS is manifest from the first ejaculations in puberty or adolescence and a secondary type, in which POIS starts later in life (2, 6).

CASE REPORT

We present the case of a 34-year-old male patient, with a very demanding job, married young, heterosexual, with two healthy children. He had no intimate relationships with other women after getting

married.

The patient had two appointments at our clinic during the last 4 years, the first in 2014 and the second in 2017. He initially presented for a "strong dysphoric status after intercourse", during the last months before his visit, "aggravating each time, from abdominal pain and nausea to generalized sickness", to which obnubilation, confusion and severe migraine were added.

The particularity of the case is that the patient had no obvious local or generalized allergic reaction, which can delay and even obscure the diagnosis. Previously he had consulted other doctors, urologists and internists, but the allergist was his last chance to have this mysterious disease diagnosed and treated.

Chief complaint: generalized post coital/post orgasmic illness over the last 4 years.

Past medical history: no history of allergy, high blood pressure (145/90 mm Hg), endoscopically diagnosed gastric ulcer, history of recurrent low urinary tract infections. The patient was asymptomatic at both consultations.

Family history: one of his children was diagnosed with atopic dermatitis. No family history of allergies or diabetes.

Current medication: occasionally, sedatives; he was using latex free condoms, with no influence on symptoms.

Self-observation and self-intervention: He was hiding the truth from his wife, refusing to deal with the problem as a couple. *He noticed that when he interrupted intercourse before reaching orgasm, symptoms did not appear*.

Physical exam*:* absence of physical signs or symptoms, no local or generalized eruption or swelling, normal blood pressure and pulse.

Lab tests showed a total IgE = 12 UI/L; seminal-fluid specific IgE = 45kUI/L (normal range < 0.35 kUI/L); CIC (Circulating Immune Complexes) = 45; serum complement = 570 UI; (++)presence of cryoglobulins

Skin prick test with his own semen resulted in a 14 mm wheal and erythema (+1), while patch test with his own semen was refused, as well as diamine oxidase (DAO) determination and the skin biopsy for mastocytosis.

Functional Diagnosis 1. A non-specific clinical test of POIS - advise the patient to stop masturbating or intercourse just before the first genital sensations of an impending ejaculation occur while having a full erection (2-17). 2. Difficult but clarifying: this is not easy to perform as one asks the patient to stop his sexual activity while having an increasing pleasure in this activity. POIS symptoms will not become manifest after this non-specific clinical diagnostic test.

Clinical diagnosis The five criteria of POIS are as follows: 1: One or more of the following symptoms: sensation of a flu-like state, extreme fatigue or exhaustion, muscle weakness, feverishness or sweating, mood disturbances and/or irritability, memory difficulties, concentration problems, incoherent speech, congested or runny watery nose, itchy eyes; 2: All symptoms occur immediately (e.g., seconds), soon (e.g., minutes), or within a few hours after ejaculation that is initiated by coitus, and/or masturbation, and/or spontaneously (e.g., during sleep); 3: Symptoms occur always or nearly always in more than 90% of ejaculation events; 4: Most of these symptoms last for about 2 to 7 days; 5: The symptoms disappear spontaneously.

Allergy diagnosis Skin prick test with autologous semen: the purpose was to objectify the skin reaction after inoculation of the semen using a protocolized intracutaneous (IC) skin-prick test. It was performed with the male's own semen (autologous

semen) and compared with a placebo skin reaction with IC saline 0.9% (6). The patient masturbated at home to produce semen. In hospital the harvested semen sample was defrosted and diluted with saline 0.9% to a concentration of 1:40,000. In addition, 0.05 mL of each dilution was IC injected at the volar side of the left forearm. The skin reaction to autologous semen and placebo were interpreted at 15 minutes after IC injections and found to be positive when the diameter of the wheal was > 5 mm with local erythema (6). The grading system of the skin reactions was as follows: I. wheal and erythema < 5 mm = negative; II. wheal 5-10 mm and erythema of 11-20 mm = 1+; III. wheal erythema of 21-30 mm = 2+; IV. erythema of 31-40 mm = 3+; and V. wheal > 15 mm or erythema of > 40 mm = 4+ (2, 6).

Positive Diagnosis Based on the functional (positive non ejaculatory test), allergy (+1 level) and clinical diagnosis (all 5 criteria were met), we made the following positive diagnosis, as being the most likely: 1. Post orgasmic illness syndrome type II (late onset) 2. Seminal Plasma Protein Allergy (SPPA) (autoimmune)

Differential diagnosis that can explain at least partially the clusters of symptoms included: 1.Seminal Plasma Protein Allergy (SPPA); 2. Systemic Mastocytosis; 3. Drug/Substance abuse; 4. Autoimmune disease with involvement of sexual activity; Unknown syndrome linked to sexual activity (other Rare forms of Post-coital Sickness).

Treatment consisted in desensitization with autologous semen. Since the patient score was +1 (wheal and erythema +14 mm), the treatment was postponed until the patient should accept a patch test and diamono oxidase (DAO) determination. All treatments should be performed in hospital and attentively surveyed by the allergist and emergency care intervention, if needed. Desensitization is made with extremely diluted autologous semen (1/40,000), by gradually higher concentrations of autologous semen. Titration are to be performed according to local skin reactions post inoculation, aiming at a wheal and flare response of 3+. This score has to be maintained for a period of at least 2 years.

DISCUSSION

Clinical data from urology and andrology reported the post-orgasmic disease status at the beginning of 2000, especially in males and after ejaculation. There are only 50 cases around the world. From the three different cases of sexual allergy, latex allergy, seminal plasma allergy and post -orgasmic disease, the latter most challenged, because there is no objective local allergic reaction and all the symptoms are subjectively presented by the patient, not obvious to the physician. The only support is the patient's observation of the inventory and timing of clinical symptoms.

In this case, we benefited from a very patient and self-aware patient who self-intervening if he had given consistent help because he performed the functional test, stopped sexual intercourse before the first genital sensations of an imminent ejaculation, complete erection. The test was positive and gave us the certainty that the allergic reaction is due to autoimmune allergies to its own seminal fluid.

The first differential diagnosis was a co-existing one, because of the high specific IgE to his own seminal plasma protein, a range of 0-0.35kUI/L being the normal values accepted for absence of SSPA. Thus, the patient has a high degree of autoimmunity to his own seminal plasma protein. We can affirm that POIS include SSPA.

The second differential diagnosis was invalidated, because of the absence of ma-

jor and/or minor criteria for mastocytosis. There were no obvious rashes or hematological changes in the number or morphology of mast cells. Also, there are no consistent data supporting the third differential diagnosis, as there was no history or clinical evidence of drug or other substance use, although clinical status was suggestive of intoxication. It is also important to establish any influence on males with POIS, of the 25-OH D vitamin deficiency, if we consider the epidemic character and the implications of this vitamin (7). Is it the semen or the seminal fluid? The question is which part of the ejaculate contains the antigen (Ag) that triggers the immunological reaction? Waldinger (3, 4, 5) reported the occurrence of POIS before and after sterilization in three men. This phenomenon means that the Ag is most likely not bound to the spermatozoa but associated with the seminal fluid. After sterilization, spermatozoa are no longer released into the genital system, but seminal fluid continues to be produced, for example by the prostate and/or the seminal vesicles.

CONCLUSIONS

We have presented an allergy case with a certain immunotherapy status, that is not associated with elevated serum total IgE or urticaria but may be associated with an autoimmune reaction in the plasma protein in the fluid seed.

Indirect clinical evidence suggests that the Ag triggering the POIS systemic reaction is not bound to spermatozoa, but to seminal the fluid produced by prostate tissue.

The crucial benefit of the case is to point out the importance of self-observation and self-intervention of the patient with POIS, for there is no possible diagnosis of this rare disease, without the contribution of the patient, since all symptoms are invalidating and restricting the visit to a doctor and the possibility of an onsite immediate allergology evaluation.

THE EVOLUTION OF CLINICO-BIOLOGICAL PROFILE OF PATIENTS UNDERGOING PROPHYLAXIS FOR POST-ERCP PANCREATITIS-A PROSPECTIVE STUDY (Abstract): In most cases, endoscopic retrograde cholangiopancreatography (ERCP) is a safe procedure. However, acute pancreatitis is the most common complication with an average incidence of 4-5.5% and a mortality of 0.5%. **Aim:** The present study aims to evaluate the incidence and the risk factors of post-ERCP pancreatitis (PEP). **Material and methods:** Patients who underwent first-time ERCP for choledocholithiasis were included in a prospective, single center trial. **Results:** The study group consisted of 98 patients (53 women - 54.08% and 45 males - 45.91%) with an average age of 63.56 ± 14.09 years old, without statistically significant differences between genders. From the 98 patients enrolled in the study, 8 patients (8.16%) developed acute pancreatitis manifested clinically after the interventional procedure (6 patients with mild - 75% and 2 with moderate forms). No severe cases have been recorded and in all the cases the evolution was rapidly favorable. Risk factor analysis demonstrated that 77.6% of the patients enrolled in the study had at least one risk factor for PEP. All patients who developed PEP (8 patients) were females; no cases of post-ERCP pancreatitis have been reported in patients under the age of 60; among the patients who developed PEP, 4 of them had normal serum bilirubin and the other 4 had hyperbilirubinemia; 66.7% of patients with excess contrast were diagnosed with PEP. **Conclusions:** The incidence of acute post-ERCP pancreatitis in our study was similar to the one reported in the literature. No severe pancreatitis was recorded, and the progression of the cases with pancreatic complications was rapidly favorable. Out of the risk factors associated with the occurrence of acute post-ERCP pancreatitis, only female sex and excess contrast substance correlated with PEP in the patients of our study. **Keywords:** ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY (ERCP), POST-ERCP PANCREATITIS (PEP), NON-STEROIDAL ANTI-INFLAMMATORY DRUGS.

Endoscopic retrograde cholangiopancreatography (ERCP) originally appeared as a diagnostic method in gallstone pathology. The subsequent diagnosis and thera-

peutic utility of ERCP has been enough demonstrated for a variety of conditions, including endoscopic treatment of biliary stones, diagnosis and management of cholangiocarcinoma and pancreatic neoplasms, and postoperative management of perioperative biliary complications (1, 2).

In most cases, this is a safe procedure, without post-procedural complications. However, there are situations where these may occur and one of the most common complications is acute pancreatitis (PEP), the average incidence is estimated at 4-5.5%, with wide variations in different studies, between 0.4% and 40%, depending on the presence of risk factors, and the reported mortality is about 0.5% (3, 4).

Despite the increasingly performing equipment used in ERCP and the wider experience of endoscopists, the incidence of PEP has remained relatively constant (5).

In this context, it is understandable the permanent interest in the study of physiopathological mechanisms and risk factors, in order to identify methods of preventing acute pancreatitis. (6)

Various therapeutic regimens have been studied to prevent this complication and, currently, European and American guidelines recommend non-steroidal anti-inflammatory drugs - NSAIDs (diclofenac, indomethacin) in various doses and modes of administration (i.v., intrarectal, etc.) (7-9). Pharmacological prophylaxis can be routinely administered or in selected cases, where risk factors for the development of pancreatic complications are identified (10, 11).

Specialty literature reports a number of risk factors involved in the occurrence of acute post-ERCP pancreatitis: those associated with patients- young age, normal serum bilirubin, acute pancreatitis post-ERCP in the past, female gender, sphincter Oddi dysfunction, and those associated with the procedure-difficult cannulation, excess injection of the contrast substance into the pancreatic duct, exaggerated use of the guide wire (5, 6).

Based on these premises, we initiated a study to evaluate the post-ERCP progression of a group of patients who received pharmacological prophylaxis with indomethacin, regardless the presence of risk factors. Patients were monitored to assess the evolution from the perspective of acute pancreatitis as a complication of interventional endoscopy.

MATERIAL AND METHODS

The prospective study was conducted in a tertiary gastroenterology center between January-July 2018. All 108 patients were over 18 years old, with biliary stones, and were proposed for inclusion in the study, due to the indication of performing an ERCP.

Exclusion criteria were the presence of acute pancreatitis or other acute inflammatory diseases at the moment of admission, contraindications for NSAIDs, recent episodes of upper gastrointestinal bleeding (less than one month), pregnancy and patient refusal.

After the initial evaluation, 98 patients were enrolled in the study that met the inclusion criteria and signed informed consent.

RESEARCH PROTOCOL

After signing the informed consent, each patient included in the study was evaluated before the intervention, to identify the risk factors through anamnesis, clinical examination, laboratory tests (complete blood count, pancreatic serum and urinary enzymes, parameters for the evaluation of inflammatory bowel disease, cholestasis

and hepatic cytolysis, renal imaging) and imaging: ultrasound and cholangial-MRI) according to the protocols in force for biliary pathology.

ERCP was performed following the standard protocol, after evaluation and anesthesia physician's opinion. Pharyngeal anesthesia was administered with 2% lidocaine spray and sedation with midazolam, ketamine and propofol. The equipment and materials used for the ERCP included a TJF 160 series (Olympus, Tokyo, Japan), standard sphincterotomes - Olympus and Boston Scientific (Marlborough, MA, United States), Visiglide hydrophilic guide wires (Olympus), and catheter extraction balloon (Boston Scientific and Wilson-Cook Medical Inc.-Bloomington, IN, United States) and / or Dormia basket from Olympus. Contrast agent was water-soluble iopamidol.

All patients were continuously monitored during the intervention, assisted by the anesthesiologist, and parameters related to the procedure (number of cannulations, amount of contrast substance, length of procedure) were recorded in the database.

All patients received 100 mg of indomethacin intrarectal, immediately after ERCP, for the prophylaxis of post-ERCP acute pancreatitis, according to the European guidelines, and administered Ringer's lactate solution (1.5 mL/kg/hr.) during the procedure and 8 hours post ERCP. After the procedure, at 6 and 24 hours, as well as in case of algic post-ERCP symptomatology, the clinical parameters (presence of abdominal pain, vomiting, fever, transit disorders) and some of the parameters (hemoleucogram, C-reactive protein, pancreatic enzymes) were evaluated. In addition, all adverse effects related to the procedure or medication administered, duration of hospitalization was recorded.

The diagnosis of PEP was set if the patient reported post-procedural abdominal pain or increased preexisting pain while pancreatic enzymes increased by at least three times the normal. Pancreatic amylase elevation of at least three times the normal value in the absence of symptomatology was classified as asymptomatic increased amylase.

Monitoring was discontinued 24 hours after ERCP if no special events were reported or after the event had been resolved if it occurred within the first 24 hours post-ERCP. In case of a complicated evolution, the patients were re-evaluated 30 days after discharge.

Data obtained from patient evaluation at all stages of monitoring (pre and post procedural) were set in a database.

The data were presented as raw values, percentages, and mean ± standard deviation. For data comparison *t-Student* test for continuous data and *Chi Square* (χ^2) or *Fisher's* exact tests were used for qualitative variables when appropriate. Results were considered significant when $p < 0.05$. Statistical analysis was conducted using *SPSS 20.0* software version.

The study protocol and the patient consent form were approved by the Ethics committee of "Grigore T. Popa" University of Medicine and Pharmacy Iasi and "Sf. Spiridon" County Clinical Emergency Hospital, Iasi, Romania.

RESULTS

The study group consisted of 98 patients (53 women-54.08% and 45 males-45.91%) with an average age of 63.56 ± 14.09 years old without statistically significant differences between genders.

Study of clinical and biological data at study inclusion

Among the clinical data recorded in the initial evaluation, the most common symp-

tom was the pain in the right hypochondrium, identified in 67% of cases, followed by jaundice (53% of patients).

Related to the biological data recorded in the initial assessment of patients, cholestasis and hepatic cytolysis were the main changes recorded, both identified in 83.7% of patients.

Study of the clinical and biological parameters evolution at 6 hours and 24 hours post ERCP

The PEP diagnosis was recorded based on the clinical examination associated with biological samples (pancreatic enzymes and parameters of inflammatory syndrome-leukocytes, C-reactive protein) monitored at 6 and 24 hours post-ERCP.

From the 98 patients enrolled in the study, 8 patients (8.16%) developed acute pancreatitis manifested clinically after the interventional procedure. It should be noted that in all cases the onset was early, less than 6 hours after the intervention, with no cases of late onset. From the patients who developed acute pancreatitis after ERCP, 6 patients were mild (75%) and 2 moderate forms. There were no severe pancreatitis and all cases had a favorable progression. No adverse effects related to study medication (digestive bleeding, rectal irritation, or allergy) have been reported.

The comparative study of pancreatic enzymes and C-reactive protein at the two monitoring periods (6 and 24 hours post-ERCP) is synthetically represented in first table. At 6 hours post ERCP, amylase increases of more than 3 times the normal value in 18.4% of patients, while in 24 hours only 8.2% of patients had values compatible with the diagnosis of asymptomatic hyperamylasemia.

TABLE I

Dynamics of clinical and biological factors at 6 and 24 hours

	At 6 hrs.	At 24 hrs.
Amylasemia		
< 3 x N	81.6%	91.8%
> 3 x N	18.4%	8.2%
Lipase		
< 3 x N	69.4%	91.8%
> 3 x N	30.6%	8.2%
CRP		
normal	49.0%	49.0%
minor increase	20.4%	20.4%
moderate increase	26.5%	22.4%
important increase	4.1%	8.2%
Clinical-biological status at 6 hours		
Absence of PEP criteria	91.8%	91.8%
PEP	8.2%	8.2%

Lipase values had a similar dynamics to amylase (tab. I), with significant improvement in 24 hours after the intervention. At 6 hours post ERCP, lipase values were

found to be 3 times higher than the upper limit of normal in 30.6% of patients, and this percentage decreased to 8.2% at 24 hours.

Also, the inflammatory status assessed by C-reactive protein determination has undergone significant variations during the follow-up: 51% of patients experienced C-reactive protein increase, more than half of them with moderate/marked elevated values. It should be noted that the inflammatory status rate was maintained in the same proportions at the 6 and 24 hours respectively.

Study of risk factors for PEP development

Another objective of the research was to determine whether there is a correlation between the occurrence of acute pancreatitis and the presence of risk factors associated with the development of PEP in the study group.

77.6% of patients enrolled in the study had at least one risk factor for PEP. We studied the presence of the risk factors recognized in the literature and we identified: female sex (45% of cases), age under 60 years (36.7%), normal bilirubin (20.4%), excess of contrast substance (12.2%) and acute pancreatitis post-ERCP in the past (4.1%) (fig. 1).

We assessed the risk of pancreatitis in the presence and absence of risk factors (fig. 2).

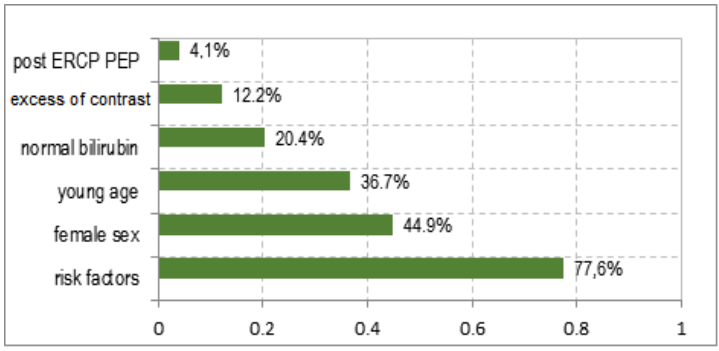

Fig. 1. The distribution of risk factors in the studied group

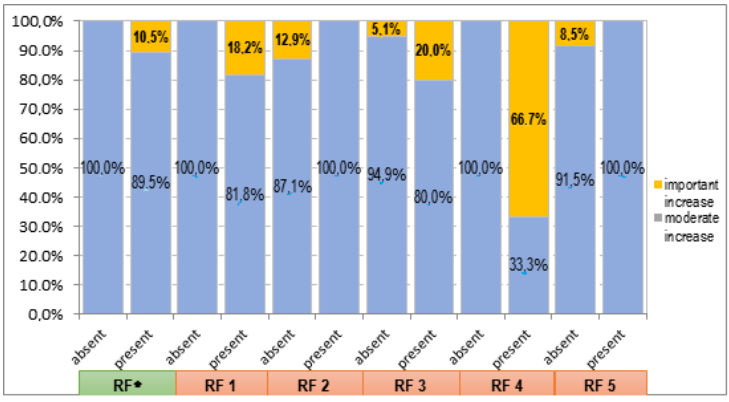

Fig. 2. The relationship between the presence of risk factors and the occurrence of PEP.

Five distinct risk factors (RF), ranging from RF 1 to RF 5, have been studied and have the following meaning:

- RF 1: female gender,
- RF 2: young age,
- RF 3: normal bilirubin,
- RF 4: Excessive contrast substance,
- RF 5: History of PEP

All patients who developed PEP were females. As a result, for 18.2% of the patients who developed the complication, female gender was a risk factor. The value is statistically significant, especially since no male patient presented the complication.

Since no cases of post-ERCP pancreatitis have been reported in patients under the age of 60, we cannot claim that young age has been a risk factor for the patients in our study group.

Also, the normal serum level of bilirubin before endoscopic intervention was not related to the risk of developing the complication. Among the patients who developed acute pancreatitis, 4 of them had normal serum bilirubin and the other 4 had hyperbilirubinemia. As a result, this did not significantly correlate with the occurrence of acute pancreatitis.

Excessive contrast substance administration correlated with the occurrence of acute early pancreatitis (in the first 6 hours): 66.7% of patients with excess contrast were diagnosed with acute pancreatitis, while none of the patients without excess of contrast substance developed the complication. Acute pancreatitis did not statistically correlate with the presence of other episodes of pancreatitis (RF5) in the past. None of the patients with a history of pancreatitis developed acute pancreatitis, whereas among those without a history of pancreatitis, 8.5% of the patients presented the complication. OR risk analysis has shown that the only significant risk factor for pancreatitis is the use of an increased amount of contrast (tab. II).

TABLE II

***Chi-square* test values to compare the presence of PEP depending on the presence of risk factors**

Clinical status	Chi-square	p	OR
RF pres. / abs.	1.261	0.261	-
RF 1 pres. / abs.	5.345	**0.021**	-
RF 2 pres. / abs.	2.529	0.112	-
RF 3 pres. / abs.	2.348	0.125	**4.625**
RF 4 pres. / abs.	31.215	**0.000**	-
RF 5 pres. / abs.	0.185	0.667	-

DISCUSSION

Numerous studies have been reported in the literature, including meta-analyzes, that have assessed the incidence of post-ERCP acute pancreatitis, as well as possible risk factors associated with the occurrence of this complication. The average incidence is estimated at 4-5.5%, with wide variations in different studies, between 0.4% and 40%, depending on the presence / absence

of risk factors (3, 4). In our study, the incidence of PEP was 8.16%. The results are similar to those reported in other studies: Cheng *et al*. reported an incidence of 2-9% in the general population and 15% in high-risk patients (12).

The patients in our group were not selected based on the presence of risk factors and they all received prophylaxis with indomethacin, according to international guidelines. These aspects may explain differences compared to other studies (13, 14).

It should be emphasized that the clinical and biological evolution of the cases that were diagnosed with PEP and asymptomatic hyperamylasemia was favorable, with the improvement of the symptomatology and biological parameters in all patients, with no severe forms or progression to worsening or death. These favorable results may have been obtained because all patients received NSAIDs prophylaxis regardless of the presence or absence of risk factors. According to the literature, prophylaxis with indomethacin is effective, reducing the incidence of acute pancreatitis and improving the clinical and biological evolution of post-ERCP cases of pancreatitis (13, 15, 16).

Another objective was to study whether the factors recognized in the literature as associated with the occurrence of acute post-ERCP pancreatitis (female sex, age under 60 years, normal serum bilirubin, excess contrast substance and personal history of pancreatitis) are associated in our group with the occurrence of acute pancreatitis (17). Risk factor analysis demonstrated that although all of the factors mentioned were present in varying proportions in the patients from the study group, only female gender and excess contrast were correlated with the occurrence of pancreatitis, OR risk assessment demonstrating that the latter influenced the most the risk of PEP.

These results, discordant compared to other published studies, can be explained by the fact that the number of patients included in the study (and implicitly those who developed PEP) is small.

CONCLUSIONS

The incidence of acute post-ERCP pancreatitis in our study was similar to the one reported in the literature. No severe pancreatitis was recorded, and the progression of cases with pancreatic complications was rapidly favorable. Out of the risk factors associated with the occurrence of acute post-ERCP pancreatitis, in the patients in our study, only female sex and excess contrast substance correlated with PEP.

THE IMPORTANCE OF ARTERIAL STIFFNESS ASSESSMENT IN PATIENTS WITH GRADE 1 HYPERTENSION (Abstract): Assessing the arterial stiffness (AS) in hypertensive patients brings complimentary information for the cardiovascular (CV) risk stratification, but current data is rather limited in mild hypertensive patients. The purpose of the study was to evaluate the association between CV risk factors and AS markers in patients with grade 1 hypertension. **Material and methods:** The study was prospective, conducted over a 14-month period and included 58 patients diagnosed with grade 1 hypertension. Patients were extensively analyzed for the presence of CV risk factors and for the determination of AS parameters – pulse wave velocity (PWV) and aortic augmentation index (AixAo). **Results:** Mean age was 63.98 ± 12.24 years, 38% males. PWV was directly associated with age ($r = 0.27$; $p = 0.03$), total cholesterol ($r = 0.33$; $p < 0.01$), LDL-cholesterol ($r = 0.25$; $p = 0.05$), SCORE risk ($r = 0.25$; $p = 0.05$) as well as with the presence of stable angina ($r = 0.31$, $p = 0.02$). AixAo was associated with age ($r = 0.35$; $p = 0.01$), systolic BP ($r = 0.51$; $p < 0.01$) and diastolic BP ($r = 0.37$; $p < 0.01$). Moreover, AixAo was positively associated with total cholesterol ($r = 0.46$; $p < 0.01$) and LDL-cholesterol ($r = 0.36$; $p = 0.01$). **Conclusions:** In patients with grade 1 hypertension, arterial stiffness markers are directly associated with age, lipid parameters, BP and SCORE risk. Therefore, it is essential to apply early specific therapeutic measures to control the CV risk factors in this group of patients. **Keywords:** ARTERIAL STIFFNESS, GRADE 1 HYPERTENSION, ENDOTHELIUM DISFUNCTION, SUBCLINICAL ATHERO-SCLEROSIS, BLOOD PRESSURE.

Arterial stiffness (AS) represents the opposite phenomenon to arterial compliance, defined by the resistance to dilation (diameter variation) determined by a force (contraction of the heart) developed on an elastic body (vascular wall). With aging, but also with the occurrence and maintenance of various conditions (e.g., arterial hypertension, stress) morphological changes occur in the arterial wall, the degradation of the middLe tunic being the first change associated with chronic increase in

AS (1-4). This change is microscopically characterized by the breakdown of the elastin and collagen fibers in the structure of the middle tunic and determines, from an ordered arrangement of the elastin blades, the appearance of fragmented, thinner structures of the elastin and a higher resistance of the collagen resulting in a calcification of the middle tunic. Macroscopically, thickening of the arterial wall appears mainly through hypertrophy, but also through the hyperplasia of smooth muscle cells, altering at last the parietal viscoelastic properties (1-5). These changes determine an increased in peripheral arterial resistance and a decrease in vascular compliance (6-8).

The increased stiffness of the arterial wall and the high rate of propagation of the pulse wave velocity (PWV) places the patient in high group of risk. The degree of AS increases with aging as well as with a number of conditions, which are associated with increased CV risk, such as high blood pressure (BP), diabetes, hypercholesterolemia and chronic renal failure (9-12).

AS has an independent predictive value of all-cause mortality and cardiovascular morbidity, of fatal and non-fatal coronary events and stroke in essential hypertension, diabetes, in patients with chronic end-stage renal disease, in elderly patients and in general to the whole population (9-13). The contribution of AS in increasing the CV risk is explained by a series of mechanisms that converge to promote ventricular hypertrophy, aggravate myocardial ischemia, ischemic stroke or renal impairment (5, 12, 14, 15). Thus, based on the AS parameters measurements we can identify the hypertensive patients at increased risk of cardiac and cerebrovascular events and who can benefit from an earlier and more aggressive cardiovascular treatment. Nowadays, this evidence led to the inclusion of the PWV measurement as a mandatory step in the evaluation of subclinical organ damage in grade 1 hypertensive subjects (16).

The aims of the current study are: - assessment of AS in patients with grade 1 hypertension; - identifying the main CV risk factors associated with increased AS in this class of patients; - the importance of AS analysis as a parameter of increased CV risk in grade 1 hypertension.

MATERIAL AND METHODS

The study was prospective, conducted over a 14-month period and included 58 patients diagnosed with grade 1 hypertension. These patients were extensively analyzed for the presence of CV risk factors as well as for the determination of AS parameters.

The exclusion criteria were the refusal of patients to participate in the study; patients with sinus rhythm disorders at the time of examination; patients who failed to record the parameters of AS; the presence of a cancer in terminal stage; major CV complications (myocardial infarction, stroke, cardiac or peripheral revascularization).

The following parameters and CV risk factors were assessed: age, gender, height (cm) and weight (kg) used to calculate the body mass index (BMI), smoker status and alcohol consumption, as well as hemodynamic parameters: systolic BP – SBP, diastolic BP – DBP and heart rate. All patients have been diagnosed with grade 1 hypertension according to the current guidelines (16). From the patient' personal history we were interested in heart failure, chronic ischemic heart disease, dilated cardiomyopathy, peripheral vascular disease, chronic kidney disease, stroke, atrial fibrillation or

diabetes.

In this study, we focused mainly on the following laboratory parameters: total cholesterol, HDL-cholesterol, LDL-cholesterol, triglycerides, urea, creatinine with determination of glomerular filtration rate (GFR). Moreover, we calculated the CV risk charts Framingham, SCORE and Q-RISK for a better stratification of the CV risk.

Using the Arteriograph® device, several parameters of AS were determined non-invasively but the focus was on PWV and the augmentation index of the aorta (AixAo).

Statistical analysis was performed in SPSS 20.0. The existence of a relationship between variables was evaluated using Pearson correlation coefficient. Descriptive data is presented as mean ± standard deviation. A p value <0.05 was considered statistically significant.

RESULTS

The patients mean age was 63.98 ± 12.24 years, and 38% were males. The main characteristics of the study group is highlighted in table I.

Regarding the medication of the patients, most of them use between 1 and 3 drugs and within the gender representation, women (22) were using more drugs compared to men (13). It is worth mentioning that 12% of patients did not consume any antihypertensive drugs (5 women compared to 2 men). Among the antihypertensive drugs, the most common were beta-blockers and diuretics, both being used by 43%, respectively 34% of participants. The frequency prescribed order was followed by angiotensin conversion enzyme inhibitors and calcium channel blockers. Angiotensin-II-receptor antagonists were used only in 12% of cases.

TABLE I

The main characteristics of the study group

Group profile	Results
Age (years)	63.98 ± 12.24
SBP (mmHg)	150.96 ± 5.96
DBP (mmHg)	85.22 ± 6.83
Years with hypertension	6.28 ± 5.57
BMI (kg/m^2)	28.73 ± 4.84
Framingham score (%)	11.30 ± 7.17
SCORE risk (%)	3.70 ± 2.52
Q-RISC (%)	20.72 ± 11,67
Total cholesterol (mg/dL)	193.46 ± 36.46
LDL-cholesterol (mg/dL)	111.73 ± 34.36
HDL-cholesterol (mg/dL)	54.75±12.39
Triglycerides (mg/dL)	141.74 ± 89.16
Urea (mg/dL)	35.31 ± 12.14
GFR (ml/min/1,73m^2)	79.26 ± 27.22
Glucose (mg/dL)	105.39 ± 31.68
PWV (m/s)	8.75 ± 1.34
AixAo (%)	31.40 ± 14.17

BP-blood pressure, BMI-body mass index, PWV- pulse wave velocity, AixAo-augmentation index of aorta

Among the study group, 51.72% of patients had stable angina, 18.97% had dilatative cardiomyopathy and 43.10% were diagnosed with chronic heart failure. More detailed information can be found in table II.

TABLE II

The presence of other CVD comorbidities in the study group

CVD	All patients	Males	Females	p value
Stroke	5.17%	0.00%	100.00%	0.23
Stable angina	51.72%	40.00%	60.00%	0.47
Chronic venous insufficiency	25.86%	33.33%	66.67%	0.45
Chronic kidney disease	1.72%	0.00%	100.00%	0.08
Diabetes	25.86%	46.67%	53.33%	0.30
Myocardial infarction	5.17%	33.33%	66.67%	0.68
Chronic heart failure	43.10%	8.00%	92.00%	**<0.001**

CVD- cardiovascular diseases

Regarding PWV and the age of the patients, we detected the presence of a statistically significant positive correlation with r = 0.27 and p = 0.03, which shows a trend of increasing PWV value with age (tab. III). A simple linear regression equation was applied to observe the degree of PWV variation with age. As a result, we obtained F = 7.82, p <0.05, R^2 = 0.0787 and therefore a change of 0.25 m/s of PWV increase with one unit in age in our study group (fig. 1).

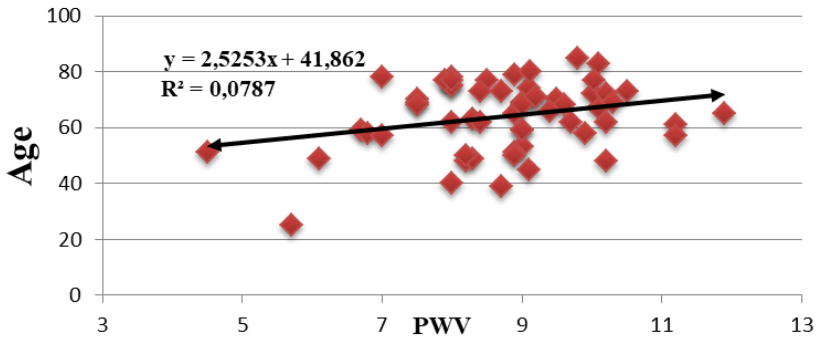

Fig.1. Positive correlation between PWV and age

As for AixAo and age we observed the presence of a positive correlation that is statistically significant with a r = 0.35 and p = 0.01 which demonstrates a tendency of increasing AixAo with growing age (tab. III). The simple linear regression equation pointed out F= 7.40, p <0.05, R^2 = 0.116 and therefore an increase directly proportional of AixAo with age (fig. 2).

Studying the relationship between PWV and total cholesterol values, a positive correlation with statistical significance was detected (r = 0.33; p < 0.01) (tab. III). A simple linear regression equation was applied to analyze the degree of cholesterol variation with PWV which indicated a p

<0.05, R^2 = 0.115 and therefore a change in PWV with 0, 1 m/s may causes a directly proportional change in total cholesterol by 0.90 mg/dL (fig. 3).

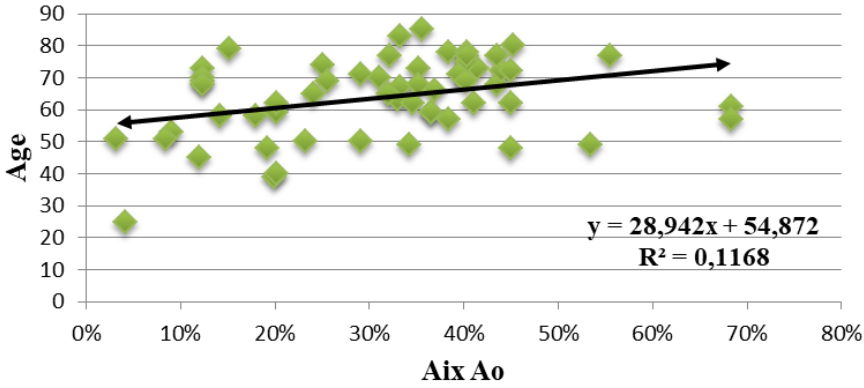

Fig. 2. Positive correlation between AixAo and age

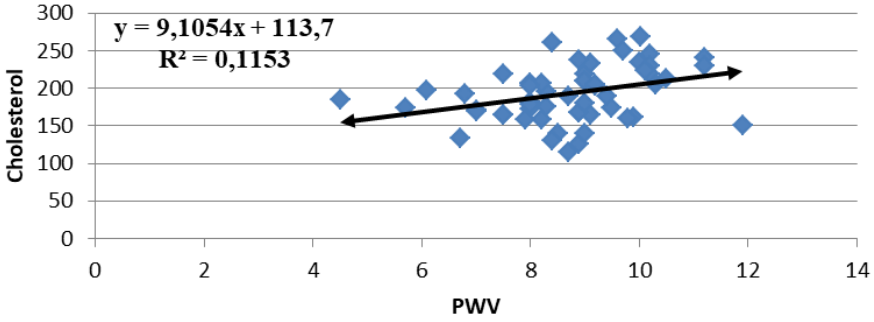

Fig. 3. The positive correlation between PWV and total cholesterol

Analysing the correlation between AixAo and total cholesterol, a positive and statistically significant correlation was detected (r = 0.46, p < 0.01). For AS parameters and LDL-cholesterol analysis, the PWV result was significantly positive (r = 0.25, p = 0.05) while for AixAo the result had increased significance (r = 0.36 and p = 0.01) (tab. III).

By analyzing the relationship between AS parameters and CV risk charts (Framingham, SCORE and Q-RISK) we obtained a positive and statistically significant correlation between PWV and SCORE risk chart (r = 0.25, p = 0.05) which may be translated into an increase in PWV values directly proportional to the increase of SCORE risk (tab. III).

By analyzing the AS markers with the associated CV pathologies, some correlations with statistical significance were obtained, especially in the case of PWV with stable angina (r = 0.031, p = 0.02).

Notably, a strong positive correlation

was observed between AixAo and SBP ($r = 0.51$, $p < 0.01$) as well as with DBP ($r = 0.37$, $p < 0.01$), but not for PWV and BP parameters (tab. III).

TABLE III
Relationship between CV risk factors and AS parameters

	PWV (m/s)		Aix Ao (%)	
	r	p value	r	p value
Age (years)	**0.27**	**0.03**	**0.35**	**0.01**
Total cholesterol (mg/dL)	**0.33**	**<0.01**	**0.46**	**<0.01**
LDL-cholesterol (mg/dL)	**0.25**	**0.05**	**0.36**	**0.01**
SCORE risk chart	**0.25**	**0.05**	0.01	0.96
Stable angina	**0.31**	**0.02**	0.29	0.11
SBP (mmHg)	0.22	0.09	**0.51**	**<0.01**
DBP (mmHg)	0.18	0.16	**0.37**	**<0.01**

DISCUSSION

In this study we aimed to analyze the impact, at an early stage, of the AS parameters on the CV status considering only patients diagnosed with grade 1 hypertension. Lately, a special interest on the structure and function of the arterial wall is increasing mainly due to the association between increased AS and CV morbidity and mortality, but also because AS has become an independent predictive marker for CV risk (9-12,17). However, current data is still limited regarding the AS in patients with small degree of hypertension, our study bringing new information in the comprehensive evaluation of these patients. Thus, we analyzed the AS markers with a series of clinical and paraclinical parameters in order to observe their importance in the evaluation of the hypertensive patients.

It is known that the process of arteriosclerosis is accentuated with aging and is even more accelerated in the presence of several physiological factors such as hypertension. In the present study, PWV is indeed significantly and directly proportional with the age of the patients. Mattace-Raso F. *et al*. confirmed that an increase of PWV is directly proportional with an increase of age on a number of 16,867 patients from 8 European countries (18). Another longitudinal study by AlGhatrif M. *et al*. (the Baltimore study) confirmed this finding on 423 women and 354 men between ages of 21 and 94 years with a more increased PWV values in men (19).

In our study, AixAo presents statistically significant correlations with the age of the patients, result that is accordance with the literature. In the ACCT (Anglo-Cardiff Collaborative Trial) study, the authors found the same increase of AixAo being directly proportional to age (20). In a meta-analysis performed by Baksi A. *et al*. including 13,770 subjects aged 4 to 91 years and aiming for the mechanism of blood pressure changes with aging and indirectly modifying AixAo, the result was a significant change in blood pressure as the aging process is progressing (21). Another study confirmed an increase of AixAo up to the age of 60, but also an increase of BP parallel to the increase in age (22).

Within the study group, the characteri-

zation of the patients was also realized from the perspective of the biochemical parameters. A significant correlation between increased PWV values and total cholesterol was obtained. Moreover, positive correlations between PWV, AixAo and elevated LDL-cholesterol levels were highlighted. Some literature data confirms the existence of this association between these parameters (23). However, other studies did not reveal a statistically significant association between PWV and cholesterol fractions or total cholesterol (24). As well, on a group of participants with ages between 65 and 84 years, the association of plasma cholesterol with the AS of large vessels is denied (25). We found no study that was focused on patients with hypertension debut as was our population.

Regarding the association of the AS markers with the CV pathologies, a significant positive correlation was obtained between the increased PWV values and the presence of stable angina. A Sutton-Tyrrell analysis of 2,248 participants in the Health ABC study revealed the association of increased PWV with 341 coronary heart disease, 94 stroke, and 181 cases of congestive heart failure (26). Another study counting 2000 patients aged over 50 showed a close relationship between PWV and CV mortality independent of previous CV events, age and diabetes (10). Laurent S. *et al*. showed that PWV is a predictor of major CV events in patients with high BP (27).

Moreover, we identified a directly proportional and statistically significant relationship between PWV value and the SCORE risk, result that was also identified on a group of asymptomatic persons (28). Similar, PWV is statistically significant in predicting the CV risk according to SCORE scale more that the Framingham scale explained by the underestimation of the real high CV risk (29).

Statistically significant associations could be observed in the case of AixAo and SBP and DBP. It can be stated that SBP determined noninvasively at the central level represents a better indicator of the process of arteriosclerosis, a fact confirmed by other studies (30) that support the need to determine central blood pressure and arterial stiffness as tests for cardiovascular risk assessment. Moreover, the direct correlation between AixAo and SBP is also confirmed by other longitudinal studies (31), our data having the particularity that investigated only grade 1 hypertensive subjects.

CONCLUSIONS

In patients with grade 1 hypertension, AS parameters are directly associated with age, total cholesterol and LDL-cholesterol. AixAo is directly associated with systolic and diastolic BP while PWV has also positive correlation with SCORE risk chart. Therefore, it is essential to apply early specific therapeutic measures to control the CV risk factors in this group of patients.

NEWS

VITAMIN D AND THE THERAPEUTIC EFFECT IN NONALCOHOLIC STEATOHEPATITIS

Nonalcoholic steatohepatitis (NASH) is a rapidly progressive component of nonalcoholic fatty liver disease (NAFLD) that can lead to advanced fibrosis, cirrhosis and hepatocellular carcinoma (HCC). This disease is a socio-economic global burden due to the diagnostic methods and lack of effective treatment. NASH represents the main cause of hepatic transplant in United States of America (USA). Vitamin D (Vit D) is a fat-soluble vitamin obtained through diet or synthesized in the skin from 7-dehydrocholesterol. It plays a major role in the pathophysiology of autoimmune diseases. Low seric levels of Vit D correlate with progression of NAFLD. The main target of this study was to show that dietary supplementation with VitD leads to the decrease of histological components in NAFLD / NASH and can improve hepatic function. This was a prospective-observational study that explores the impact of low-fat control diet (LFD) or high-fat/high-sugar Surwit diet (HFSD) and vitamin D3 association in inflammation of steatosis and liver fibrosis. The study was conducted on mice for a 16-week period. The quantity of vitamin D administrated was 500 UI per kg which represents half of the amount recommended by the National Research Council. The results showed a that preventive administration of high dose of Vit D on HFSD mice has counteract gain and adipose tissue expansion, improving liver steatosis, and led to reduced overall NASH activity with a non-significant liver fibrosis remission. In recent years, the treatment for NASH is of great scientific interest, and the information from this study can be extrapolated to the general population, as a way of reducing steatosis and inflammation as well as liver fibrosis, because NAFLD is a major public health problem with an endemic manifestation (Jahn D, Dorbath D, Kircher S, *et al*. Beneficial effects of vitamin D treatment in an obese mouse model of non-alcoholic steatohepatitis. *Nutrients* 2019; 11 (77), doi: 10.3390/nu11010077).

EVALUĂRI ASUPRA REZULTATELOR OBŢINUTE ÎN TERAPIA PERITONITELOR ACUTE. EXPERIENŢA PE 317 CAZURI CLINICE ÎN SPITALUL JUDEŢEAN SUCEAVA

ASSESSMENT OF ACUTE PERITONITIS TREATMENT RESULTS. SUCEAVA COUNTY HOSPITAL 317 CASES EXPERIENCE (Abstract): The aim of this study was to identify prognostic factors for morbidity, mortality and long term outcome and to analyze the different management modalities for acute diffuse peritonitis. **Material and method**: A clinical retrospective study was carried out on a series of 317 cases with acute peritonitis; admitted in the General Surgery Department, Hospital of Suceava, between 2006-2009. **Results**: There were 212 men (67%) and 105 women (33%) aged between 1 and 89 years. Preoperative concomitant disease was present in 31% of patients: cardiac disease was most common. The most common etiology was acute appendicitis in children 74 of cases (27.6%). Overall, 44 patients died during hospitalization. The cause of death was sepsis and multiple organ failure in 30 patients; malignancy in 8 patients and cardiac failure in 6 patients. Source control at the initial operation was possible in 282 of the patients (89%), of those 28 patients (9%) needed re-intervention. In 32 patients (10%), source control was not possible at the initial operation. **Conclusion**: This study emphasis the importance of prompt surgical treatment and shows the impact of adapting antibiotic treatment. **Key words**: PERITONITIS, MORTALITY, SURGERY, ANTIBIOTHERAPY

INFLUENCE OF COMORBIDITIES ON QOL IN PATIENTS ON CHRONIC RENAL REPLACEMENT THERAPY

INFLUENCE OF COMORBIDITIES ON QOL IN PATIENTS ON CHRONIC RENAL REPLACEMENT THERAPY (Abstract): Little is known about the quality of life (QoL) and survival in patients on chronic dialysis therapy in Romania. **Aim**: To investigate the impact of comorbidities on QoL in patients with end-stage renal disease (ESRD). **Material and methods**: The 254 patients aged 22-88 years old included in the study were divided into two group as follows: 243 hemodialysis (HD) patients and 11 peritoneal dialysis (PD) patients. QoL was measured by RAND 36-Item Health Survey 1.0 (SF-36). Scores for all dimensions are expressed on a 0-100 scale. Higher scores indicate better health status. Information on comorbid conditions and medical history were obtained from patients' medical and dialysis records. We focused on four chronic diseases: diabetes mellitus (DM), chronic liver disease (CLD), uremic anemia (UA) and oncologic diseases (OD). **Results**: Eighty-two percent of ESRD patients included in this study had at least one comorbidity. Uremic anemia was the most common secondary diagnosis in both groups (HD 63.1%, PD 54.5%) followed by CLD (HD 24.2%, PD 9.1%), DM (HD 14.3%, PD 18.2%) and OD (HD 4.1%, PD 9.1%). DM had a strong negative impact on the physical domain of QoL (p=0.05). **Conclusions**: Comorbidities seem to influence QoL in ESRD patients. **Keywords**: DIALYSIS THERAPY, QUALITY OF LIFE, DIABETES MELLITUS.

Health-related quality of life (HRQoL) is identified as a vital health outcome for studies evaluating the quality of healthcare, assessing the influence of illness and analyzing cost-effectiveness (1, 2). Various studies have shown that socioeconomic status (3), dialysis program, ethnic group, sex, mobility, comorbidities (e.g., diabetes), malnutrition, depression (4) and unsuccessful previous renal transplant affect the QoL of dialysis patients (5). DM is a major cause of ESRD and is recognized as an important comorbidity among ESRD patients; but the situation gets worse because DM has its own complications which affect the QoL of an individual. In Romania, inadequate dialysis, high depression rate, malnutrition and anemia (3) all affect the QoL of HD patients. Chronic disease have a strong impact on physical health, financial status, social life, and ability to perform activities of daily living, but no quantitative evaluation of any of these has been done in Romania. Therefore, the aim of this study was to investigate the impact of comorbidities on QoL of patients with ESRD, especially with respect to DM in HD patients.

MATERIAL AND METHODS

This prospective cross-sectional observational study was performed in in October 2015 in a single dialysis unit, B. Braun Avitum Botosani, Romania. It included a total of 254 hemodynamically stable patients divided into two groups: 243 (95%) patients on HD therapy and 11 (5%) patients on PD therapy. Inclusion criteria were: 1) on regular HD for more than three months; 2) age > 18 years; 3) no hospitalization or acute illness in the preceding 3 months; 4) no psychiatric disorders (such as mental retardation or dementia). Informed consent was obtained from all participants before enrolment in the study. All patients filled out the SF-36 questionnaire.

QoL was measured using the RAND 36-Item Short Form Health Survey (version 1.0) which assesses eight health concept: 1) Physical Functioning (PF); 2) Role limitation due to Physical Functioning (RPF); 3) Bodily Pain (BP); 4) General Health Perception (GH); 5) Vitality (VT); 6) Social Functioning (SF); 7) Role Limitation due to Emotional Functioning (RLE); 8) Mental Health. Raw score of each dimension are transformed into a score ranging from 0-100. Higher scores indicate better health. Information on comorbid conditions and medical history were obtained from each patient medical and dialysis records.

Statistical analysis was made with *SPSS 16.0* and a p value < 0.05 was considered significant. Baseline characteristics of the study group, analyzed using descriptive statistics, are presented as mean ± standard deviation (SD), as appropriate. We used the t-test and Mann Whitney non-parametric test (U) to compare the variables between both groups. Pearson's correlation is used to assess the magnitude and direction of association between comorbidities and SF-36 questionnaire. Kruskal-Wallis test was used for the comparative study of SF-36 scores between patients with different degrees of secondary affections.

RESULTS

Mean age of the study group sample was 57.79 ± 14.30 years, without significant group differences (p = 0.248). In HD group we identified a significantly inverse correlation between age and SF-36 scale scores (tab. I). Sex distribution was relatively balanced (55.1% males, 48.9% females). Females scored significantly lower for all SF-36 scales except for VT, MH and SF (tab. II, fig. 1). Mean dialysis duration was 64.78 ± 47.72 months and had no significant impact on QoL score (tab. III).

Eighty-two percent of our study cases had at least one comorbidity besides the main diagnosis of ESRD (fig. 2). UA was the most common secondary diagnosis in both groups (HD 63.1% *vs.* PD 54.5%) followed by CLD (HD 24.2% *vs.* PD 9.1%), DM (HD 14.3% *vs.* PD 18.2%) and OD (HD 4.1% *vs.* PD 9.1%) (fig. 2). We investigated the impact of each comorbidity on SF-36 scales. We focused first on DM. In the majority diabetic HD patients (HD-DM+) the SF-36 scale scores were below 50 (PF, RPH, VT, MH, SF, GH general QoL score) (fig. 3). The most affected domain was PF which showed a statistically significant difference between non-diabetic and diabetic HD patients (54.37± 37.30 and 40.85± 38.75, respectively, p=0.05) (tab. IV). In PD patients diagnosed with DM there were non-systematic fluctuations of SF-36 scores compared to those without this additional diagnosis (fig. 4). REP remained almost constant, the most affected by the presence of this disease being the RPF score. In HD patients with CLD the only influenced scale was GH (p=0.04) (tab. IV). UA and OP showed no significant influence on QoL dimensions in both groups (tabs. IV, V).

DISCUSSION

Chronic diseases like diabetes mellitus, liver disease or oncologic diseases affect various aspects of human life (6). Long-term treatment, financial support and special care are required to deal with such diseases. In ESRD, the main goal of chronic dialysis therapy is to improve QoL, which is usually measured in terms of physical, psychological and social wellbeing. In this study we have evaluated HRQoL among chronic dialysis patients with different types of comorbidities by SF-36 questionnaire. Although HRQoL among patients undergoing chronic dialysis in our country was studied previously (7), there are no data regarding the influence of comorbid conditions on QoL in these group of patients. Our results show that the more chronic diseases the patient had, the more likely he/she was to have poor SF-36 scores. Yang *et al.* (8), in 2010, studied HRQoL in Singapore and revealed that low Charlson comorbidity index was significantly associated with better HRQoL in Asian patients with renal failure. Despite the fact that in our study age was not an exclusion criterion, significantly better scores on SF-36 scales in younger patients were not recorded. Dialysis duration followed a similar trend, and no significant correlation with SF-36 scales was found. On the other hand, males showed significantly higher scores for all SF-36 dimensions. Regarding the comorbid condition, it is known that diabetes is one of the leading cause of ESRD worldwide. We found that HRQoL and both its physical and mental health components were lower in diabetic HD patients compared to the non-diabetic HD group. Notably, the diabetic HD patients reported the lowest level of perceived physical functioning. The various diabetes complication, such as cardiac problems, peripheral vascular diseases and foot amputation, all contribute to impaired physical

abilities and consequently result in low QoL (9,10). In a recent study conducted in Iran (11), diabetic foot infection and catheter infection accounted for 11% and 14% deaths, respectively. With progression of dialysis therapy, the features of cardiac and vascular diseases accelerated in diabetics and it has been reported that the frequency of diabetic foot became 2-5 times higher in dialysis patients in contrast to pre-dialysis period (9,10). Martínez-Castelao *et al.* (12) also found that diabetic patients starting dialysis in Spain have lower HRQoL in contrast to non-diabetics. Diabetic dialysis patients are characterized by reduced self-rated physical health, high prevalence of diabetic complications, and sometimes a relatively good mental health.

Dialysis modality has been identified as a major risk factor of infection with hepatitis B virus (HBV) and hepatitis C virus (HCV), with significantly higher seroconversion rates in HD compared with PD patients (13, 14, 15). In our study, 24% of the HD patients were found to have HBV or HCV infection and only 9% in the PD group. When evaluating the impact of CLD on SF-36 scale scores, a significantly lower score was found only on general health perception. The cross-sectional study by Rostami *et al.* (16) which included 4101 patients from 103 dialysis units, showed that not only general health and physical activity were preserved but also health perception was better among viral hepatitis patients on HD. On the other hand, in another study performed in Turkey (17) which included only 165 HD patients of which 83 were anti-HCV antibody positive revealed that HCV infection impairs QoL, especially in mental aspects. It is important to mention that in our study the QoL of viral hepatitis patients on IFN (interferon) treatment was not determined. It is known that IFN has several adverse effects that can impair QoL during the treatment (18). Akyuz *et al.* (19) performed a study after IFN treatment to evaluate real QoL and revealed that general health and physical activity which were poor, and anxiety were higher in the IFN treated patients as compared with untreated patients. These contradictory results may be explained by the fact that HRQoL in HD patients with chronic hepatitis was evaluated by different questionnaires: Nottingham Health Profile which is a measure of distress in six domains (sleep, energy, pain, mobility, emotional reaction and social isolation) and SF-36, a general questionnaire with eight domains for measuring function and well-being.

CONCLUSIONS

In this study we have evaluated HRQoL among patients on renal replacement therapy with different types of comorbidities using SF-36 questionnaire. We found that lower HRQoL indicated more underlying comorbidities. Diabetes mellitus had a negative impact on physical functioning domain of QoL, possibly in the context of underlying vascular disease under the detrimental effect of uncontrolled glucose level. Chronic liver disease was found to affect only general health perception. Identifying these factors will inform the timely implementation of interventions to improve the quality of life of these patients. Given the small sample size, the data obtained by us in the peritoneal dialysis group are limited, and in order to assess QoL among this group of patients a multicentric study must be conducted.

STUDY ON PREVALENCE OF ASSOCIATION BETWEEN METABOLIC SYNDROME COMPONENTS (Abstract)**:** In Europe, approximately 25% of population are estimated to have metabolic syndrome (MS), with similar prevalence values in Latin America. In general, the prevalence of the metabolic syndrome increases with age with nearly 40% of people aged 60 and older meeting the diagnostic criteria. **Material and methods**: The purpose of this study is to evaluate the prevalence of associations between metabolic syndrome components to find a pattern applicable to patients with this pathology. The study was conducted on a total of 1,528 patients over 18 months, from 01.06.2017 to 31.12.2018, within a general practitioner (GP) medical office, being an epidemiological case-control study. **Results**: Studying the distribution of *Harmonized I* diagnostic criteria in the research group, we obtained the following data: 15.7% of subjects were included into MS with three components (MS3); 6.9% of the participants fall into the MS with four components (MS4); 2.87% of the patients included in the study group all five components of the metabolic syndrome (MS5). Out of a total of 203 women diagnosed with MS, we identified the presence of five-component MS in 10.83% of MS patients, while 31.03% were diagnosed with MS4. **Conclusions**: Early diagnosis of MS by the family doctor may reduce the cardiometabolic risk, the costs it generates, and could increases patients' quality of life. **Keywords**: METABOLIC SYNDROME, OBESITY, CARDIOMETABOLIC RISK.

In Europe, approximately 25% of people are estimated to have metabolic syndrome (MS), with similar prevalence values in Latin America (1). It is also considered an emerging epidemic in developing East Asian countries, including China, Japan, and Korea (2, 3). The prevalence of metabolic syndrome in East Asia may range from 8-13% in men and between 2-18% in women, depending on the population and definitions used. This is believed to be due to the "westernization" seen in recent years in the Asian continent, pertaining mainly to a diet high in carbohydrates and fats and a less active, sedentary lifestyle (4, 5, 6).

In general, the prevalence of the metabolic syndrome increases with age with nearly 40% of people aged 60 and older meeting the diagnostic criteria. Due to the increase in pediatric obesity and diabetes mellitus, the metabolic syndrome is becoming more prevalent in younger population thus it is no longer considered a disease of the elderly (7, 8).

Currently, there are two ways to control cardiometabolic risk factors included in MS: lifestyle management (weight loss by fighting sedentary disease and adopting an antiatherogenic and hypocaloric diet) and drug therapy (9, 10). Although drug therapy aims to control cardiometabolic risk factors according to medical guidelines adopted, achieving therapeutic targets is difficult to obtain. Under these conditions, the introduction of new diagnostic and therapeutic methods based on the etiopathogenesis of MS could improve the quality of life of MS patients and would lead, in the long run, to an increase in average life expectancy (11, 12).

The aim of this study is to evaluate the prevalence of associations between metabolic syndrome components to find a pattern applicable to patients with this pathology.

MATERIAL AND METHODS

The study was conducted on a total of 1,528 patients over 18 months, from 01.06.2017 to 31.12.2018, within a general practitioner (GP) medical office, being an epidemiological case-control study. For the inclusion of patients in metabolic syndrome, the *Harmonized I* diagnostic criteria were applied.

According to *Harmonized I* , MS is defined by the presence of at least three of the five components of the metabolic syndrome: central obesity; triglycerides ≥ 150 mg/dL (1.7 mmol/L) or specific treatment; HDL - cholesterol < 40 mg/dL (1.03 mmol/L) in men and < 50 mg/dL (1.29 mmol/L) in women or specific treatment; systolic blood pressure ≥ 130 mmHg and / or diastolic blood pressure ≥ 85 mmHg or specific treatment; Glycemia *à jeune* ≥ 100 mg/dL (5.6 mmol/L) or diabetes mellitus previously diagnosed. Abdominal circumference (AC) was not included as a mandatory diagnostic criterion.

The components of the metabolic syndrome research used the clinical and laboratory data obtained by clinical examination and laboratory determinations.

The inclusion criteria in the study were: age over 18 years, voluntary participation in the study and MS diagnosed based on the Harmonized criteria I. Exclusion criteria from the study were: age under 18 years, denial to participate in research and women during pregnancy or lactation.

The study protocol was applied according to the recommendations of the Ethics Committee of "Grigore T. Popa" University of Medicine and Pharmacy Iasi, a biding with the ethic norms of the European Community with regard to the investigations carried out on the patients.

Statistical analysis. For statistical processing of the studied parameters we used the programs *Microsoft Office Excel Medcalc Statistical Software 97-2003, SPSS version 16* (Statistical Package for Social Sciences) and the application - 14.3.3. The t-Student test was used to compare the continuous variables in the studied population and comparing the category variables we performed with the Chi square test. In order to compare the proportions calculated in the study we determined the z - test. Were mentioned both the 95% confidence intervals (CI) and the statistical signifi-

cance thresholds (p). P value less than 0.05 was considered statistically significant.

To determine the MS score we applied the diagnostic criteria and we calculated the MS score for each subject: 0 - the absence of the criterion, 2 - the presence of the criterion. The MS score had values in the range of [6-10].

Depending on the number of existing diagnostic criteria, patients who presented three criteria (MS score = 6) were diagnosed with MS with three components (MS3), those who presented four criteria (MS score = 8) were included in MS with four components (MS4), and those who presented all five diagnostic criteria (MS = 10) were classified as MS5 with five components (MS5). MS calculated average score according to the *Harmonized I* criteria was 3.16.

RESULTS

Since our study investigated the prevalence of metabolic syndrome in the population of a general practitioner (GP) medical office in Iasi, Romania, we preferred the use of the *Harmonized I* definition for MS because it includes criteria adapted to a unitary approach of MS, thus allowing to study an increased number of patients diagnosed and who are following correct treatment according to Medical Practice Guidelines. We obtained a 25.39% metabolic syndrome prevalence, in line with reported data for our geographical area.

Studying the distribution of *Harmonized I* diagnostic criteria in the research group we obtained the following data: 15.7% (95% CI: 13.83-17.87) of subjects were included into MS with three components (MS3); 6.9% (95% CI: 5, 55 - 8.23) of the participants fall into the MS with four components (MS4); 2.87% (95% CI: 2.09-3.86) of the patients included in the study group all five components of the metabolic syndrome (MS5) (tab. I).

TABLE I

Distribution of subjects according to the *Harmonized I* criteria

Gender	Classification of subjects according to *Harmonized I*				Total
	Non-MS	MS3	MS4	MS5	
F	610	118	63	22	813 (53%)
M	530	123	41	21	715 (47%)
TOTAL	1,140	241	104	43	1,528

Analyzing the data from the previous table, we calculated that out of 185 male (12.1%) patients diagnosed with MS, 11.35% were classified as MS5, 22.16% in MS4 and 66.49% were diagnosed with MS3.

Regarding female patients, out of a total of 203 (13.3%) women diagnosed with MS, we identified the presence of five-component MS in 10.83% of MS patients, while 31.03% were diagnosed with MS4. A percentage of 58.14% of females which were enrolled in MS had three components of metabolic syndrome (MS3) (fig.1). Also, for each association of MS components diagnosed according to the Harmonised I criteria, we calculated the prevalence within MS (tab. II).

Analyzing the MS components in the 388 (25.4%) patients diagnosed with MS according to the *Harmonized I* criteria, we found that among all components central obesity is the best represented (80.72%, 95% CI: 76.44-84.52), followed by hypertension (78.92%, 95% CI: 74.53-82.87), hypertriglyceridemia (69.15%, 95% CI: 64.30-73.71), hypo-HDL-cholesterolemia (61.23%, 95% CI: 58.76-68.54) and hyperglycemia (56.81%, 95% CI: 51.73-61.79).

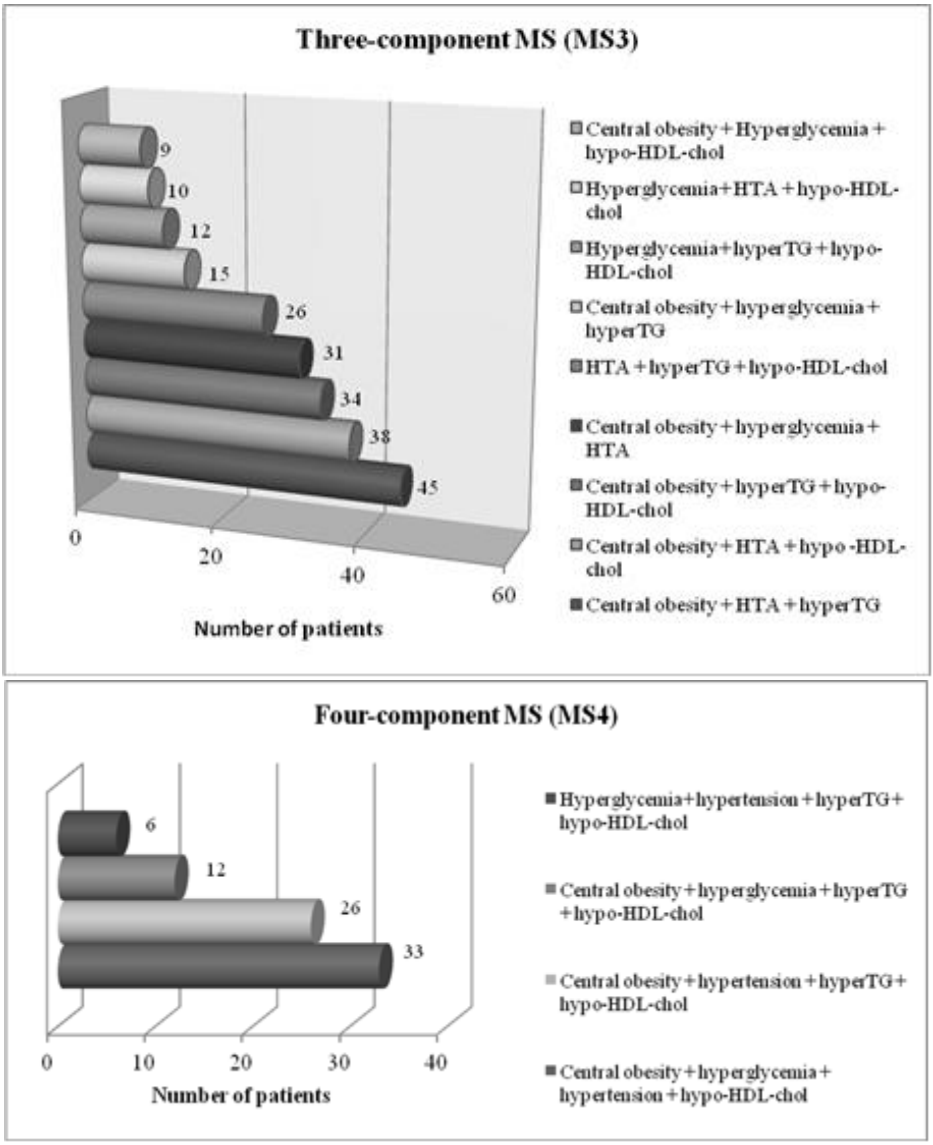

Fig. 1. Associations within the metabolic syndrome
*The chart does not include the 43 patients with MS with 5 components

TABLE II

Prevalence of associations between MS components (according to the *Harmonized I* criteria)

	Number of patients	The percentage in MS patients (95% CI)	The prevalence in the study population (95 % CI)
Three-component MS (MS3)	240	61.95% (54.38–70.29)	15.75% (13.83-17.87)
Central obesity + hypertension + hypertriglyceridemia	45	11.54% (8.44–15.48)	2.94% (2.14-3.93)
Central obesity + hypertension + hypo -HDL-cholesterolemia	38	9.79% (6.91–13.40)	2.48% (1.75-3.40)
Central obesity + hypertriglyceridemia + hypo-HDL-cholesterolemia	34	8.74% (6.05–12.21)	2.22% (1.53-3.10)
Central obesity + hyperglycemia + hypertension	31	7.96% (5.41–11.31)	2.02% (1.37-2.87)
Hypertension + hypertriglyceridemia + hypo-HDL-cholesterolemia	26	6.68% (4.36 –9.79)	1.69% (1.11-2.49)
Central obesity + hyperglycemia + hypertriglyceridemia	15	3.85% (2.15-6.36)	0.98% (0.54-1.16)
Hyperglycemia+ hypertriglyceridemia + hypo-HDL-cholesterolemia	12	3.08% (1.59-5.38)	0.78% (0.40-1.37)
Hyperglycemia+ hypertension + hypo-HDL-cholesterolemia	10	2.57% (1.23–4.72)	0.65% (0.31-1.20)
Central obesity + Hyperglycemia hypo-HDL-cholesterolemia	9	2.31% (1.05–4.39)	0.58% (0.26-1.11)
Four-component MS (MS4)	105	26.74% (21.84-32.39)	6.79% (5.55-8.23)
Central obesity + hyperglycemia + hypertension + hypo-HDL-cholesterolemia	33	8.22% (5.62-11.16)	2.09% (1.43%- 2.95)
Central obesity + hypertension + hypertriglyceridemia + hypo-HDL-cholesterolemia	26	6.42% (4.15- 9.48)	1.63% (1.05-2.41)
Central obesity + hyperglycemia + hypertriglyceridemia + hypo-HDL-cholesterolemia	12	3.08% (1.59-5.38)	0.78% (0.40-1.37)
Hyperglycemia+ hypertension + hypertriglyceridemia + hypo-HDL-cholesterolemia.	6	1.54% (0.56- 3.35)	0.39% (0.14-0.85)
Five-component MS (MS5) Central obesity + Hyperglycemia + hypertension + hypertriglyceridemia + hypo-HDL-cholesterolemia	43	11.31% (8.22-15.18)	2.87% (2.09-3.86)
TOTAL (MS3 + MS4 + MS5)	388	100%	25.42% (22.96- 28.08)

DISCUSSION

The diagnosis of MS involves highlighting its components. Different European and international commissions have proposed various diagnostic criteria, mainly determined by the specializations and concerns of the members of the respective groups.

The MS is a complex pathophysiologic state that originates primarily from an imbalance of calorie intake and energy expenditure but also affected by genetic/epigenetic make up of individual, predominance of sedentary lifestyle over physical activity, and other factors like quality and composition of food and composition of gut microbiota (13).

MS is also defined as the coexistence of abdominal obesity, atherogenic dyslipidemia, high blood pressure and insulin resistance. In a study, Grundy consider that obesity, especially abdominal obesity, is an essential component of metabolic syndrome (14). Abdominal obesity is a most common component of MS in our study, the data being in accordance with those found in the literature.

The condition is progressive, starting with values of risk factors at the boundary line of normal and possibly progressing to categorically pathological values. The MS has been associated with a variety of individual variables, including demographics, lifestyle, clinical measures and physical performance (15).

Civil societies, outside of the strict medical community, need to help disseminate the awareness of the huge impact of MS on the overall health in the global community.

Literature data show that MS is about three times more common than diabetes and the global prevalence can be estimated to be about one quarter of the world population. In other words, over a billion people in the world are now affected with SM (14). In our study it is a less frequent component, the data not being in accordance with those found in specialized literature.

Patient motivation leading to improved lifestyle adherence is a key factor in achieving reduction in metabolic syndrome components (16).

CONCLUSIONS

Applying the MS score along with the implementation of an electronic diagnostic record contributes to rapid, efficient and standardized information processing and to accurate diagnosis of MS in primary care. In this study, most of the patients were diagnosed with three-component metabolic syndrome, followed by patients with four and five component metabolic syndrome. We found that among all components, central obesity is most commonly represented, followed by hypertension, hypertriglyceridemia, hypo-HDL-cholesterolemia and hyperglycemia. Early diagnosis of MS by the family doctor may reduce the cardiometabolic risk, the costs it generates, and could increases patients' quality of life.

PRIMARY CUTANEOUS PERIVASCULAR EPITHELIOID CELL TUMOR (PEComa). CASE REPORT AND REVIEW OF THE LITERATURE (Abstract): PEComas represent a family of uncommon mesenchymal tumors that can develop on the skin and also can affect internal organs with a distinct immunophenotype that typically shows both myogenic and melanocytic differentiation. We present the case of a 49 years old female patient, from urban area, who was hospitalized in Dermatology Clinic Craiova for the presence of a 2 cm diameter tumor, round shaped, reddish-pink, with smooth surface, located on the internal site of the right thigh. The diagnosis of primary cutaneous PEComa was confirmed histopathologicaly and immunohistochemically and from the clinical point of view it represents a challenge for the dermatologist. **Keywords:** PEComa, PERIVASCULAR EPITHELIOID CELL TUMOR, DERMOSCOPY.

PEComas (perivascular epithelioid cell tumors) are mesenchymal tumors that can develop on the skin and also can affect internal organs. Those tumors have histological and immunohistochemical common features. PEComas are tumors expressing both melanocytic and myogenic markers with non-specific clinical features (1-3).

CASE REPORT

We present the case of a 49 years old female patient, from urban areas, was hospitalized in Dermatology Clinic Craiova for the presence of a 2 cm diameter tumor, round shaped, reddish-pink, with smooth surface, located on the internal site of the right thigh (fig. 1).

Fig. 1. Clinical image

Past medical history: appendectomy at six years old. She first noticed the tumor about a year ago. The evolution was to slowly increase in size. The patient did not follow any local or general treatment. At clinical examination we found a patient with BMI = 22.3 kg/m^2, Photo type II, without any pathological changes.

During hospitalization, the following investigations were performed:

Dermoscopic examination revealed a pale pink tumor, with the absence of structural elements (fig. 2).

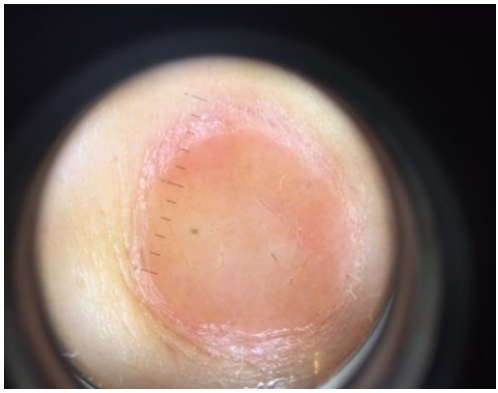

Fig. 2. Dermoscopic features: pale pink tumor, with the absence of structural elements

Under local anesthesia with lignocaine 1%, tumor excision was performed, with oncological safety margins, suture and dressing. The tumor was sent for microscopic examination.

Histopathology revealed atrophic epidermis, dermis and hypodermis cell proliferation with clear cytoplasm, some bi- and multinucleate in a fine collagenous stroma (fig. 3). Immunohistochemical examination is recommended for establishing the origin of the tumor.

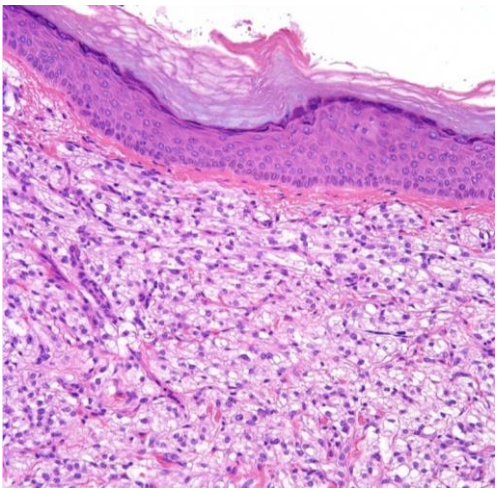

Fig. 3. Histopathological aspects of PEComa

Atrophic epidermis, dermis and hypodermis cell proliferation with clear cytoplasm, some bi- and multinucleate in a fine collagenous stroma

Immunohistochemical examination revealed tumor proliferation composed from epithelioid cells with abundant pale eosinophilic cytoplasm, and slightly hypertrophic, round-oval shaped nucleus, some with visible nucleoli; minimum tumor stroma with numerous thin-walled vessels. HMB45 (human melanoma black), CD44, CD10 were positive in tumor proliferation. S100, Melan A, cytokeratin AE1 / AE3, CK8 / 18, p63, SMA (smooth muscle actin specific), ER (estrogen receptor), chromogranin, synaptophysin were negative in tumor cells. CD34 was positive in numerous intratumorally vessels. Ki67 (proliferation factor): 3%. Histopathological diagnosis is PEComa (perivascular epithelioid cell tumor).

We also performed abdominal ultrasound for our patient, which revealed in the liver the presence of multiple hyperecho-

genic images with hemangiomatous aspect with maximum size of one cm; uterus increased in size; without fluid in the abdominal cavity; without lymphadenopathy. It is recommended to perform thorax, abdomen and pelvis CT. In our case no pathological changes were found.

Based on the medical history, physical examination and investigations, we established the diagnosis of Primary cutaneous perivascular epithelioid cell tumor (PEComa). Differential diagnosis, for our case, was made with dermatofibroma, achromic melanoma and cutaneous metastases. Treatment and management consisted of surgical excision of the tumor. The patient will be assessed every 6 months in the first year after surgery and annually on the long term.

DISCUSSION

In 1996 Zamboni introduces the term PEComa which contain a group of tumors formed from perivascular epithelioid cells located in different organs and tissues, including the skin (4). Tumor origin is explained by three hypotheses: origin from cells with common features with undifferentiated cells developed from neural crest; myoblast origin, with a molecular mutation triggering melanogenesis; pericytes origin (vascular cells).

Primary cutaneous PEComas are rare tumors, usually located on the lower limbs but cases have been described on the upper limbs and thorax. They are usually found in adult women. In a review of literature published in 2016, 34 cases of primary cutaneous perivascular epithelioid tumor were described (5, 6). The evolution of cutaneous PEComas is usually benign, but cases with malignant evolution were described. Folpe has described criteria for malignant PEComas (2005), which include: tumor diameter more than 5 cm; infiltrative tumor growth with high nuclear grade; the presence of necrosis; mitotic activity; tumor with aggressive clinical evolution. The tumor is considered benign when no malignant criteria are present. When there are two or more criteria present, the tumor is considered malignant. If one criteria is present, the risk of malignancy is uncertain (5, 7).

PEComas diagnosis is certified with histopathology and immunohistochemistry examination. In terms of histopathology are well defined dermal tumors composed of epithelioid cells with rich, clear or slightly granular cytoplasm, with central nucleus. The cells are arranged perivascular (4, 8, 9, 10).

Immunohistochemically is characteristic that tumors are positive for melanocytic markers: HMB 45 = human melanoma black (the most sensitive and is expressed by all PEComas published), Melan A, and MITF (microphthalmia transcription factor) and smooth muscle markers: desmin and SMA. Primary cutaneous PEComas are negative for epithelial markers (4, 9, 10, 11).

Charli-Joseph Y *et al.* on a clinicopathological and molecular reappraisal analyzed the clinicopathological features of 8 primary cutaneous PEComas. They were evaluated for DNA copy number changes and for initiating mutations common in melanocytic neoplasms. Primary cutaneous PEComas were assessed using immunohistochemistry, DNA sequencing and comparative genomic hybridization. There were no chromosomal copy number changes or initiating mutations were identified. Primary cutaneous PEComas are a diagnostic challenge, so it was propose that MIT fac-

tor, NKIC3, SMA, desmin, bcl-1, cathepsin K, and 4E-binding protein 1 to be used when evaluating a possible primary cutaneous PEComa (12). Stuart reported 5 additional cases of this rare entity. All showed classic histologic features and expression of either HMB-45 and/or Melan-A/MART-1 (13).

PEComas differential diagnosis can be made with dermatofibroma - the clinical aspect is of brownish tumor, often located on the legs and is slowly growing; cutaneous metastasis - the incidence is 0.7 to 5% of all cancers internal; achromic melanoma represents 10-12% of de novo melanomas; *Xhantomas tuberosus* - dysmetabolic yellowish painless tumors, associated with hyperlipidemia (6, 14, 15, 16). So far, the curative treatment of primary skin PEComas is represented by surgical excision (6).

CONCLUSIONS

The diagnosis of primary cutaneous PEComas is confirmed histopathologicaly and immunohistochemically and from the clinical point of view represents a challenge for the dermatologist.

Given the possibility of malignant evolution, patients will be follow-up continuously after the surgical cure of the tumor.

Our case had a benign evolution, without the presence of malignant signs at 6 months after the tumor excision.

NEWS

A REVIEW OF PATIENT AND PROVIDER SATISFACTION WITH TELEMEDICINE

According to the Office of the National Coordinator for Health Information Technology, telemedicine (TM) can be defined as "the use of electronic information and telecommunications to support and promote long-distance clinical health care, patient and professional health-related education, public health and health objective measures including clinical outcomes, cost (both direct and indirect), and availability. In addition, patients and providers need to be at least as satisfied with their telehealth experience as they are with in-person visits. If this is not achieved, they both will refuse to use TM and as a result, adoption of the new technology will languish. The use of TM will expand only if patients and providers are at least as satisfied with it as they are with in-person visits. Since deviations from expected care can result in reduced satisfaction regardless of the quality of the visit or objective medical outcomes, it is important to understand and to help form those expectations when possible. Patients consistently report 95-100% satisfaction rate with TM when compared with in-person appointments. They tend to cite the convenience of decreased travel times and costs as the main drivers for satisfaction with TM. Providers tend to be satisfied with TM if they have input into its development, there is administrative support, the technology is reliable and easy to use, and if there is adequate reimbursement for its use. Satisfaction with TM is necessary for adoption of this new technology. To improve satisfaction, it is important to consider factors that drive it both for patients and for providers. CARDIAC PACING IN ACUTE RIGHT VENTRICULAR MYOCARDIAL INFARCTION (Abstract): Isolated acute right ventricular myocardial infarction is rarely seen, being associated in 30-50% of cases with acute inferior myocardial infarction, providing an increased mortality rate. Due to coronary anatomy, an acute occlusion of the culprit artery at different levels may produce conduction disturbances that require temporary or permanent cardiac pacing. Furthermore, adding biventricular dysfunction it may generate cardiogenic shock. **Material and methods:** Our study analyzes the conduction disturbances requiring cardiac pacing in patients with acute right ventricular myocardial infarction admitted in "Prof. Dr. George I. M. Georgescu" Cardiovascular Diseases Institute, Iași, between January 2013 and January 2018. **Results:** 41 patients from 183 with acute right ventricular myocardial infarction presented significant conduction disturbances, 33 requiring cardiac pacing. 48.48% of them had acute occlusion of proximal right coronary artery, having significant statistical association (p=0.0414), requiring cardiac pacing and conduction disturbances (p<0.001). 15.15% of patients presented cardiogenic shock having in most cases acute occlusion of proximal right coronary artery. **Discussion:** Patients with acute right ventricular infarction present in their evolution conduction disturbances related to the occlusion of the proximal right coronary artery in most cases, associating right ventricle dysfunction, our study results being in concordance with literature data. **Conclusions:** Our study, even being an observational one, shows that the presence of a right ventricular myocardial infarction must alert the medical teams in order to consider a possible temporary cardiac pacing to provide a safe transportation to PCI center and a permanent pacemaker after myocardial revascularization.
Keywords: CARDIAC PACING, RIGHT VENTRICULAR MYOCARDIAL INFARCTION.

Acute right ventricular myocardial infarction is associated in 30-50% of cases with acute inferior myocardial infarction (1), meanwhile isolated right ventricular infarction is rarely seen (2).

Being still an underdiagnosed pathology, the association between acute inferior myocardial infarction and right ventricular infarction has a higher mortality comparing with the cases without right ventricle in-

volvement (25-30% versus 6%) (3).

The responsible coronary artery for right ventricular infarction (*"culprit lesion")* is in majority of cases the right coronary artery or the left circumflex artery, depending on the coronary dominance (4).

Studies that include patients with inferior and right ventricle myocardial infarction revealed a high incidence of sustained ventricular tachycardias (16%), with a high rate of conduction disturbances, including complete atrioventricular block (17%) and severe bradycardia (9%), cardiac pacing being necessary in 18% of cases (5).

The anatomical explanation is that the right coronary artery irrigates not only the sinoatrial node and a part of the atria (6), but also the atrioventricular node, therefore an acute occlusion of the upper segment will block the normal impulse pathway to the ventricles. The rapidly revascularization of the artery may avoid a pacemaker implantation (7, 8).

A metanalysis that analyzed the right ventricular myocardial infarction involvement revealed a higher incidence of ventricular tachyarrhythmias and conduction abnormalities in patients with acute inferior and right ventricular myocardial infarction, also with an increased rate of cardiogenic shock and death (9).

Another study showed a higher percentage of cardiogenic shock in the right ventricle involvement and inferior myocardial infarction compared with single inferior myocardial infarction (32% *vs.* 5%) (10), which may be explained by a low biventricular output that is related to a lower heart rate (significant bradycardia or bradyarrhythmia) associated with extensive infarcted area and with proximal occlusion of right coronary artery (11).

Echocardiographic parameters such as tricuspid annular plane systolic excursion (TAPSE) is used to evaluate the right ventricular function, with a cut-off value of 17mm (12), being an easy and feasible measurement parameter, but it mostly measures the longitudinal ventricular contraction. Doppler tissue measurements and right ventricle fraction area change are needed, as well as, for more accurate diagnosis echo procedure, the right ventricle longitudinal strain (13).

MATERIAL AND METHODS

Our study analyzes the incidence of conduction disturbances that require cardiac pacing in patients with right ventricular infarction, corroborating with coronary angiography, cardiac performance parameters and mortality.

We included patients admitted in the Surveillance and Advanced Treatment Unit for Critically Cardiac Patients from "Prof. Dr. George I. M. Georgescu" Cardiovascular Diseases Institute, Iași, between January 2013 and January 2018.

The including criteria consisted in patients with acute right ventricular myocardial infarction and we excepted from analysis acute coronary syndromes other than acute ST- elevation right ventricular myocardial infarction and patients with history of surgical myocardial revascularization. We continued to select the patients that were temporary and/or permanent cardiac electrical stimulated, analyzing the survival rate, the coronary arteries involvement, cardiac performance, TAPSE and the need of surgical revascularization.

Statistical Analysis

Data analysis was performed using *SPSS version 25* software (IBM, NY). Quantitative variables were reported as

mean values ± standard deviation, meanwhile qualitative as case numbers and percent (n %). The qualitative variables association was measured using *Chi-square Pearson* or Yates tests. The comparison of quantitative variables was evaluated based on the *Mann-Whitney* U Test results. Survival analysis was calculated using *Kaplan-Meier* evaluation. For each time moment death rate probability was calculated. Signification value level (p - value) calculated in the performed tests was considered for $p < 0.05$.

RESULTS

A total of 183 patients with acute inferior and right ventricular myocardial infarction were included, 72.13% male.

The mean age of patients was 64.8±11.6 years with significant values (p = 0.000005) smaller in men (62.5±11.5) comparing with women (70.9±9.4). 22.4% (41 cases) from them presented significant conduction disturbances, 37 patients (20.2%) having complete heart block and 4 patients (2.18%) with high degree atrioventricular block.

A group of 33 patients (18.03%) required cardiac pacing, having a mean age of 70.21±10.3, with minimum values of 46 years and maximum of 86 years (fig. 1). Mean hospitalization period was 9.18±4.5 days and 63.63% of them were men (21/33 cases).

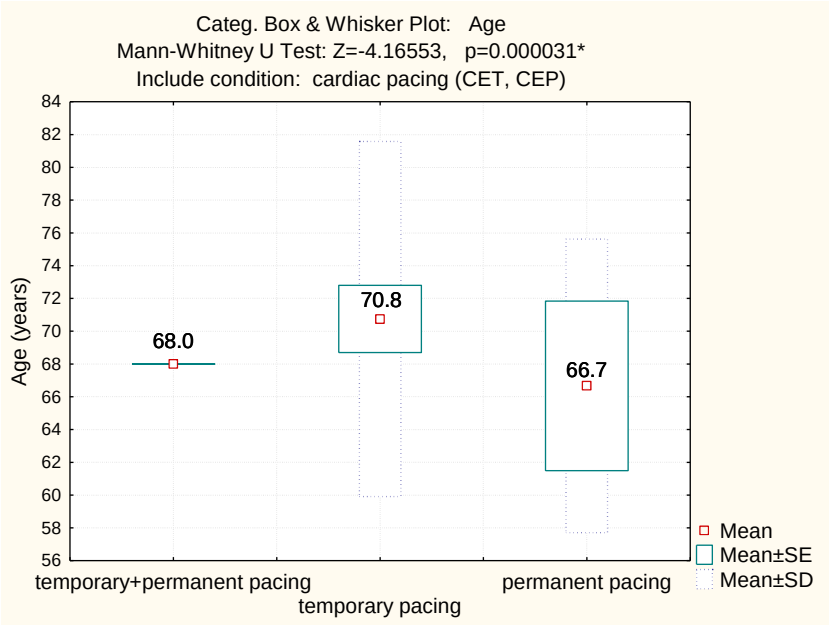

Fig. 1. Mean age value depending on cardiac pacing type

30 temporary pacing procedures were performed, 29 for complete or high degree atrioventricular blocks and 1 for ventricular tachycardia (with antiarrhythmic treatment being necessary), and from them 2 were permanently stimulated. Furthermore, 5 patients required permanent pacing, 3 of them without previous temporary support.

In the cardiac paced group, the most frequent comorbidities were arterial hyper-

tension (51.51%), diabetes mellitus (33.33%, insulin dependent (9.09%) and under oral antidiabetic drugs (18.18%)), and chronic kidney disease (36.36%). However, it was not found a significant association between comorbidities and required cardiac pacing (tab. I).

16 patients from those requiring cardiac pacing (48.48%) had acute proximal right coronary artery occlusion, meanwhile 1 patient (3.03%) presented a 99% stenosis at the same site.

7 patients (21.21%) were diagnosed with acute occlusion of the right coronary artery in the second segment of the vessel and two other patients (6.06%) were diagnosed with 95% and 99% stenosis of the same segment. Ultimately, the distal involvement of the right coronary artery was seen in 4 patients (12.12%).

Acute occlusion of the proximal right coronary artery presented a significant association (p=0.0414) with requiring cardiac pacing (tab. II), being also demonstrated a significant association with conduction disturbances (p<0.001).

TABLE I

Univariate and multivariate logistic regression analysis for cardiac stimulation required depending on the presence of comorbidities

Comorbidities *vs.* required cardiac pacing	Univariate logistic regression				Multivariate logistic regression			
	Odd ratio	C.I. 95%		*p*-value	Odd ratio	C.I. 95%		*p*-value

(*) Marked effects are significant at p<0.05								

TABLE II

The Evaluation of association between Acute occlusion of the proximal right coronary artery and Conduction disturbances that required cardiac pacing

Requiring cardiac pacing	Acute occlusion of the proximal right coronary artery		Test Statistic (t) ‡	*p*-value*
	Yes (n=61)	No (n=122)		
Temporary pacing / Permanent pacing, n (%)	16 (26.23%)	17 (13.93%)	4.1590	0.0414*
Temporary pacing, n (%)	16 (26.23%)	14 (11.48%)	6.4588	0.0132*
Permanent pacing, n (%)	2 (3.28%)	3 (2.46%)	0.1028	0.7591
	Conduction disturbances			
	Yes (n=41)	No (n=142)		
Temporary pacing / Permanent pacing, n (%)	28 (68.29%)	5 (3.52%)	78.205	<0.001*
Temporary pacing, n (%)	26 (63.41%)	4 (2.82%)	80.872	<0.001*
Permanent pacing, n (%)	3(7.32%)	2(1.41%)	4.1793	0.4092*
(‡) Yates Chi-square *(*) Marked effects are significant at p<0.05*				

The coronary angiography also revealed the implication of the left anterior descending artery in 24.24% cases (8 patients) and the left circumflex artery in 21.21% cases (7 patients), in addition to the right coronary artery lesions. Tricoronary involvement was seen in 15.15% cases, left main stenosis in 6.06% and the need of cardiac bypass procedure in 9.09% of the total number of patients requiring cardiac pacing.

Left ventricle ejection fraction varied between 15% and 56%, with a mean value of 38.92%±11.25 (mean± standards). Also, mean TAPSE value was 12.42±3.21 mm.

TABLE III

Lifetable for the evaluation of the post-therapy survival rate in the study groups

Lower Limit For Time (days)	Cumulative Proportion Surviving (%)	
	Temporary pacing	Permanent pacing
1.0	100	100
2.6	92.72	100
4.3	92.72	100
6.0	88.41	100
7.6	88.41	100
9.3	**82.52**	100
11.0	82.52	100
12.7	82.52	100
14.3	82.52	100
16.0	82.52	100

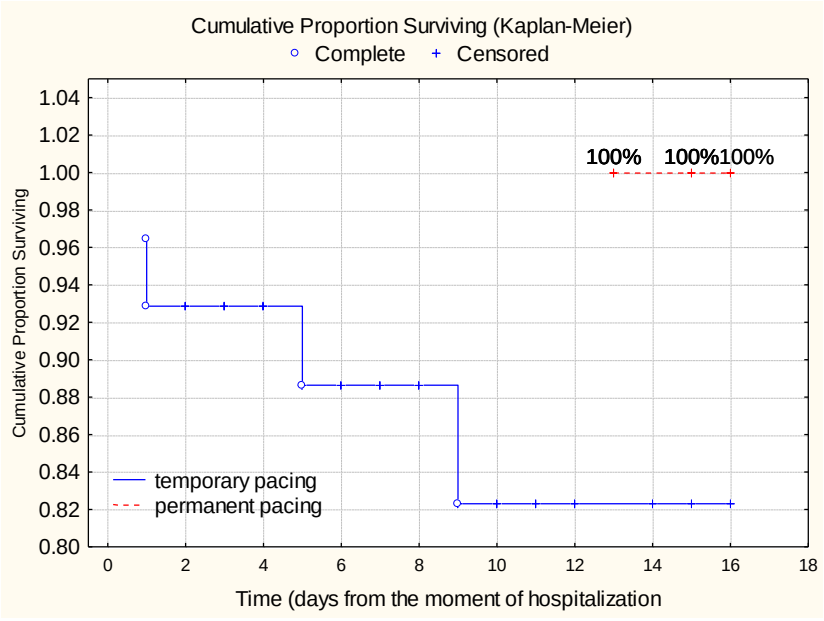

Fig. 2. The Kaplan-Meier survival curves. Survival rate estimation (days) from the admission time depending on the required cardiac pacing

15.15% of cases presented with cardiogenic shock (15/33 cases), 4 of them with acute proximal occlusion of the right coronary artery and the fifth case with acute occlusion of the circumflex artery and 90% stenosis of the right coronary artery in the second segment.

The survival rate in cardiogenic shock was 100%, PCI procedures with drug eluting stents being performed. In this group of 5 patients the mean value of left ventricle ejection fraction was 31.872%±12.8, with a mean TAPSE value of 11±2.82 mm.

The survival rate in temporary paced patients was 82.52%, at 16 days of admission, meanwhile in permanent pacing 100% (tab. III, fig. 2).

7 patients did not undergo stenting procedure due to the fact that 3 of them refused the intervention, 1 case was unsuccessful because of the inadequate coronary anatomy, 1 with cardiac surgery indication, 1 with unsignificant atherosclerotic lesion (40%) and atrial fibrillation and 1 with severe systolic disfunction and cardiac arrest at admission with no response on cardiopulmonary resuscitation.

DISCUSSION

Patients with acute inferior and acute right ventricular myocardial infarction present in their evolution a high incidence of conduction disturbances1 that may be correlated with the occlusion of the culprit artery which in most cases is the right coronary artery.

In our study the highest incidence of conduction delays in patients with acute right ventricular myocardial infarction was seen in cases with proximal occlusion of the right coronary artery, in concordance with literature data (14).

Also, cardiogenic shock was seen in 15.15% of the patients that needed cardiac pacing, associated in most cases with acute proximal occlusion of the right coronary artery, with a mean TAPSE value of 11±2.82 mm, comparing with patients without cardiogenic shock, where TAPSE was 12.42±3.21 mm.

The main consequence of the association of acute right ventricular infarction with acute inferior myocardial infarction is the wider necrotic field process of the myocardial tissue, thereby the necessity of sustaining drugs and filling improvement for maintaining an appropriate cardiac pump function increase.

We believe that the presence of the acute right ventricular myocardial infarction must alert the medical team to be prepared for an eventual transcutaneous or transvenous electrical cardiac pacing, in order to provide a safe transportation to the nearest PCI center and to predict a potential need for a permanent pacemaker.

CONCLUSIONS

Our study has limitations and strengths, being an observational study on patients with acute inferior and right ventricular myocardial infarction, without having a comparator.

In our opinion, acute right ventricular myocardial infarction associated to acute inferior myocardial infarction brings a high rate of conduction disturbances and biventricular disfunction, which may generate the appearance of cardiogenic shock.

Its rapid diagnosis in prehospital phase may improve patients short- and long-term outcomes, but further studies are yet to come.

THE RISKS OF HEPATOCELLULAR CARCINOMA AND VARICEAL BLEEDING AFTER HCV ERADICATION WITH DIRECT-ACTING ANTIVIRAL THERAPY: A PROPENSITY SCORE ANALYSIS (Abstract): The combination paritaprevir/ritonavir, ombitasvir, and dasabuvir (PrOD), which achieves a high sustained virologic response (SVR) rate and few side effects, has dramatically changed the outcome of hepatitis C virus (HCV) infection. The risk of hepatocellular carcinoma (HCC) and variceal bleeding in patients treated with interferon (IFN)-free direct-acting antivirals (DAAs) is unknown. The aim of this prospective study was to evaluate the rate of HCC and variceal bleeding and identify prognostic factors for decompensation/complications in HCV-1b-infected patients with compensated liver cirrhosis following treatment with PrOD with or without ribavirin. **Material and methods**: A total of 483 HCV patients received PrOD treatment. Patients with a history of HCC were excluded from the study. Prior antiviral therapy was identified in 59% of patients. Patient data were collected at baseline, at the end of treatment (EoT), at 3 months after EOT (SVR) and during an 18-month surveillance period. Patients were divided into two age groups: <60 years (233 patients) and ≥60 years (250 patients). **Results**: The median observation period was 540 days. During this period, HCC developed in 18 patients (3.7%) and variceal bleeding developed in 9 patients (1.9%). A Propensity score matching analysis found no significant difference in the incidence of HCC (p= 0.078) or variceal bleeding (p=0.426) between the two groups. The mean serum AFP levels decreased in the young group (baseline=19.44 ng/dL, SVR=4.57 ng/dL) and the elderly group (baseline=4.52 ng/dL, SVR=10.69 ng/dL). Edge of decompensation and previous esophageal varices were significantly associated with the risk of variceal bleeding. **Conclusions:** The risk of HCC (5.3%) and variceal bleeding (2%) development in elderly patients (≥60years) following viral eradication by IFN-free DAA therapy may follow a specific pattern. **Keywords:** DIRECT ACTING ANTIVIRALS, HEPATITIS C VIRUS, HEPATOCELLULAR CARCINOMA, VARICEAL BLEEDING.

The treatment of hepatitis C virus (HCV) with direct-acting antivirals (DAAs) has significantly changed the approach to patient selection. Interferon (IFN)-free regimens offer an important benefit for patients who are difficult to treat such as liver cirrhosis (1). DAAs have been found to be safe and effective in all patients, including those with hypoalbuminemia or thrombocytopenia, with the exception of patients with decompensated cirrhosis (2, 3). For the 1b genotype, which represents approximately 75% of all infections, an IFN-free therapeutic regimen achieved a sustained virologic response (SVR) in more than 95% of cases considered difficult to treat (elderly patients and those with compensated or decompensated liver cirrhosis, renal failure, or obesity) (4, 5). Based on data reported by clinical trials, SVR correlates with a decrease in mortality, a survival rate in formerly HCV-infected patients comparable to that of the general population, amelioration of portal hypertension, and reduced risks of hepatic disease decompensation and hepatocellular carcinoma (HCC) (6). Among cirrhotic patients with HCV, an annual incidence of HCC of up to 7% was reported (7). Some studies found that IFN- and DAA-based antiviral treatments reduced the risk of HCC (7-9), whereas others found no effect (9). The risk of variceal bleeding after DAA treatment remains unknown.

The aim of this study was to evaluate the risk of HCC and variceal bleeding and identify prognostic factors for decompensation/complications in HCV-1b-infected patients with compensated liver cirrhosis following treatment with paritaprevir /ritonavir, ombitasvir, and dasabuvir (PrOD) with or without ribavirin.

MATERIAL AND METHODS

Patients selection

Between December 1, 2015 and July 31, 2016, patients eligible for the National Insurance House reimbursement programme on PrOD treatment were prospectively enrolled via a regional antiviral therapy register. Patients with compensated HCV cirrhosis (Child-Pugh class A), genotype 1a or 1b, and severe liver fibrosis (METAVIR score 4) were eligible. Patients previously treated with IFN and ribavirin who recorded a lack of virologic response, virologic breakthrough or relapses were considered for PrOD treatment. Patients with decompensated HCV cirrhosis (defined as the presence of ascites, jaundice, variceal bleeding, hepatic encephalopathy; Child-Pugh class B or C) or the presence of HCC or dysplastic liver nodules were excluded. Only patients who achieved SVR were included in this study. We further defined a subgroup of patients who, at the time of therapy initiation, had characteristics that indicated potential decompensation-edge of decompensation group - Child-Pugh class A, score 6 and/or esophageal varices.

Treatment

Patients received the PrOD regimen, with or without ribavirin, for 12 weeks (in the case of genotype 1b HCV cirrhotic patients). The PrOD regimen administered daily included 25 mg ombitasvir, 150 mg paritaprevir, and 100 mg ritonavir in combination with 500 mg dasabuvir. Ribavirin doses of up to 1200 mg daily, adjusted according to hemoglobin level, were added.

Patients evaluation

Patients were evaluated at baseline, at the end of treatment (EoT), at SVR (12 weeks after the completion of treatment) and every 12 weeks until the end of the

follow-up (18 months post-SVR). Data collected prospectively included demographics, medical history, blood tests (full blood count, INR, ALT, AST, bilirubin, creatinine, AFP and HCV RNA quantitative test) and abdominal ultrasonography. The METAVIR score was evaluated using FibroMax™ or liver biopsy. FibroMax™ is a combination of five non-invasive diagnostic tests including FibroTest, ActiTest, SteatoTest, NashTest and AshTest. This method is used to diagnose hepatic fibrosis, viral necro-inflammatory activity, hepatic steatosis, severe alcoholic steatohepatitis (in alcoholic patients) and non-alcoholic steatohepatitis (in overweight, diabetic, or Insulin-resistant patients) (10). The FibroMax™ score is calculated using an algorithm based on a patients' sex, age, weight, height, and specific blood biomarkers (ALT, AST, GGT, haptoglobin, blood glucose, lipids, apolipoprotein A1, alpha-1-macroglobulin) (11).

Liver enzymes and quantitative viral load for HCV were re-evaluated at EoT and SVR (12). SVR was defined as undetectable HCV RNA at 12 weeks after the completion of treatment (11).

Patients found to have high AFP levels (≥20 ng/mL) underwent computed tomography (CT) and/or magnetic resonance imaging (MRI). Patients without suspicion of HCC according to the Liver Imaging Reporting and Data System (LI-RADS) criteria, or evidence of dysplastic nodules requiring surveillance, received antiviral treatment. During follow-up, HCC diagnosis required either a positive ultrasound with confirmation on a second dynamic imaging modality CT or MRI or a diagnostic biopsy (13). Patients who developed variceal bleeding were treated according to the current clinical guidelines (14). The diagnosis of variceal bleeding was confirmed by upper digestive endoscopy, performed in all patients in the first 12 hours from the bleeding event.

Patients were stratified into two groups based on age (<60 years and ≥60 years).

Outcomes

HCC occurrence and variceal bleeding were considered events of interest in both study groups.

Statistical analysis

Continuous variables were evaluated by descriptive statistics and described as the mean (±SD) or median.

Categorical values were expressed as percentages. Student's t-test was performed to compare the mean of continuous variables.

A propensity analysis was performed to match the patients one-to-one by age group (<60 years and ≥60 years (15, 16). Variables entered in the propensity model included BMI, serum albumin, platelet counts, leukocyte counts, AST, ALT, AFP and GGT levels, gender, edge of decompensation status, esophageal varices, comorbidities, T2DM and arterial hypertension.

The risks of HCC and variceal bleeding were analyzed using Cox multivariate analysis in the subgroup of patients matched by propensity score.

Statistical analysis was performed using *SPSS 20.0* software (SPSS Inc., Chicago, IL, USA). A p-value ≤0.05 was considered statistically significant.

This prospective study was performed according to the Declaration of Helsinki and international guidelines for observational studies. Written inform consent was obtained from each patient before starting the study. The study was approved by the National Ethics Committee of Medicines and Medical Devices (17).

RESULTS

Patient characteristics

A total number of 483 consecutive patients who completed the PrOD regimen were evaluated. The baseline characteristics of these patients are described in tab. I. All patients were diagnosed with severe liver fibrosis (F4 METAVIR score), and in 59.0% of cases, patients were previously treated with IFN. One hundred ninety-nine of cases (41.2%) were identified to be on the edge of decompensation. None of the patients were lost during the follow-up.

TABLE I

Baseline Characteristics of HCV Patients (n = 483)

Variable		Parameter
Gender	Male (n = 220)	45.5%
	Female (n = 263)	54.5%
Age (yrs.) (mean ± SD)		59.18 ± 8.30
Weight (kg) (mean ± SD)		76.79 ± 14.94
Height (cm) (mean ± SD)		165.96 ± 0.19
BMI (kg/m^2) (mean ± SD)		27.77 ± 4.19
Edge of Decompensation	Yes (n = 199)	41.2 %
	No (n = 284)	58.8 %
Esophageal Varices	Yes (n=135)	28.0%
	No (n=348)	72.0%
Comorbidities	Yes (n=215)	44.5%
	No (n=268)	55.5%

Patient characteristics by age group (<60 years and ≥60 years) are found in tab. II. There were no statistically significant differences between the two groups except for gender, comorbidities and arterial hypertension.

TABLE II

Clinical Characteristics of Young (<60 years) *vs.* Elderly (≥60years) Groups in 483 Unmatched Cases

Parameter	Young Group (<60 years old) n = 233	Elderly Group (≥60 years old) n = 250	p-value
Gender (Male/Female)	128/105	92/158	<0.001
BMI (kg/m^2)	28.30 (16.80-41.40)	27.12 (19.50-40.63)	0.367
Albumin (g/dL)	4.06 (3.10-5.25)	3.91 (3.04-4.97)	0.248

Comorbidities (Yes/No)	18.66 % / 31.24%	23.64 % / 26.46%	0.038
T2DM (Yes/No)	6.51 % / 43.39 %	7.81 % / 42.30 %	0.506
Arterial Hypertension (Yes/No)	8.46 % / 41.43 %	14.32 % / 35.80 %	0.004

There was no significant intergroup difference in any of the analyzed parameters except gender and concomitant diseases. Ninety young patients and 109 elderly patients were on the edge of decompensation (p = 0.262).

HCC and variceal bleeding incidence

During the observation period, HCC developed in five out of 233 (2.14%) patients in the <60-year-old group and 13 out of 250 (5.2%) patients in the ≥60-year-old group (p=0.077). An analysis of the effect of gender revealed no significant differences between the ≥60-year-oldgroup (p=0.39) and the <60-year-old group (p=0.45). The *male : female ratio* of HCC incidence was 2.5 : 1. The distribution of

events of interest (HCC and variceal bleeding) in different study subgroups are presented in tab. IV and V.

The incidence of HCC was significantly elevated in patients with high levels of AFP (> 7 ng/mL). Mean serum AFP levels decreased in the < 60-year-old group from baseline (19.44 ng/mL) to SVR (4.57 ng/mL). The corresponding mean serum AFP levels found in the ≥60-year-old group were moderate (baseline 14.52 ng/mL, SVR 10.69 ng/mL).

TABLE IV

Annual risk rate of HCC post SVR

Age	N (%)	Edge of decompensation	Compensated	Previous IFN	No previous IFN

Variceal Bleeding (N; %)	4 (1.71%)	4 (4.44%)	0	4 (6.66%)	0
Annual Risk Rate (ARR; 95% CI)	0.81 (0.327; 2.045)	3.00 (0.525; 17.149)	0.33 (0.088; 1.256)	1.50 (0.520; 4.323)	0.50 (0.106; 2.355)
≥60 years old	250 (51.75%)	104 (21.53%)	141 (29.19%)	75 (15.52%)	175 (36.23%)
Variceal Bleeding (N; %)	5 (2.0%)	5 (4.8%)	0	5 (6.66%)	0
Annual Risk Rate (ARR; 95% CI)	1.14 (0.590; 2.226)	0.11 (0.007; 1.177)	0.64 (0.435; 0.950)	0.33 (0.027; 4.186)	0.50 (0.296; 0.844)

Multivariate analysis revealed that probability of HCC development at 540 days was higher in the ≥ 60-year-old group (5.4%) than in the <60-year-oldgroup (1.7%) (Figure 1).

Propensity scores matching analysis found an increased probability of HCC development in the ≥60-year-old group (5.3%) compared to the <60-year-oldgroup (1.8%), with no significant differences observed between the groups (p=0.078) (fig. 2).

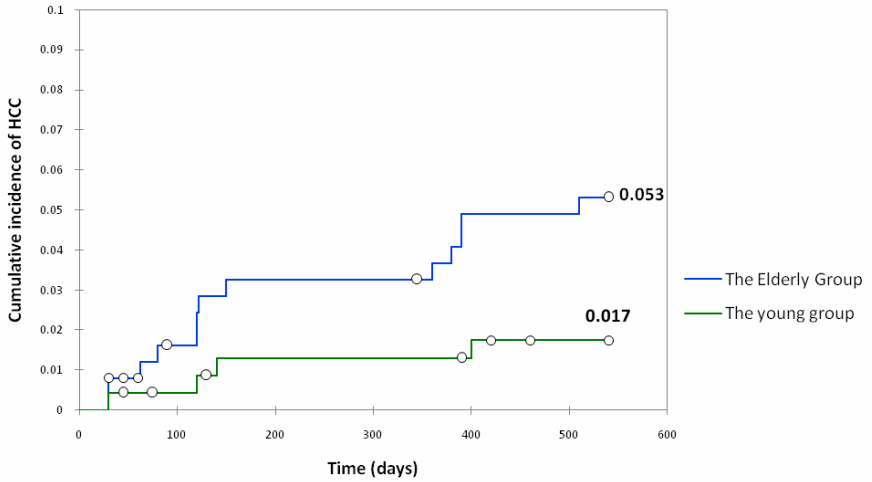

Fig. 1. Cumulative HCC Development-Before Propensity Score Matching

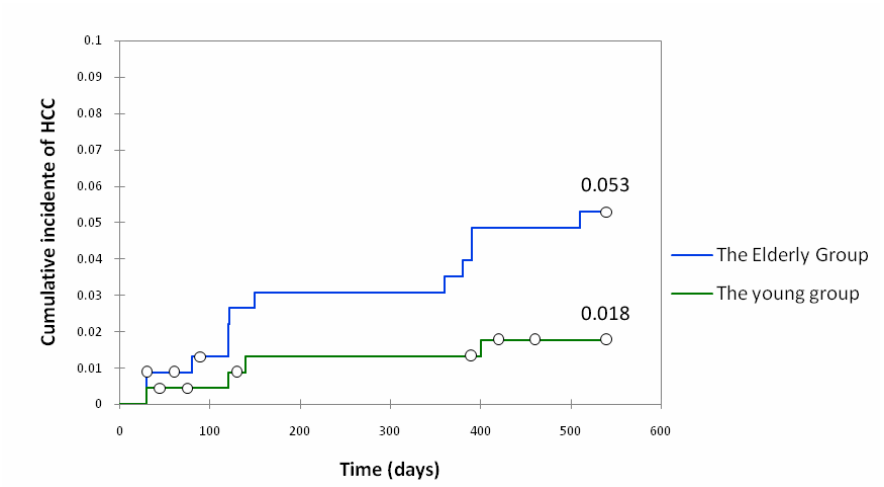

Fig. 2. Cumulative HCC Development in Propensity Score Matched Patients

Variceal bleeding was recorded in nine (1.9%) of all cases. None of the patients without previous described esophageal varices has bled. Esophageal varices at

baseline were found in 25.7% of <60-year-old patients and 30.0% of ≥60-year-old patients. There was no difference regarding the variceal bleeding rate between elderly group and the young group (2.0% *versus* 1.7%, p=0.818). Evolution of variceal bleeding was favorable under standard treatment and no mortality was recorded.

The edge of decompensation had significant influence on HCC development in elderly group. Eight patients (14.50%) in the elderly group were at the edge of decompensation and developed HCC *vs.* 1 patient (1.8%) in the young group (p=0.011).

DISCUSSION

Our study included a homogeneous large cohort of HCV genotype 1b liver cirrhosis patients, followed-up for 18 months in tertiary academic centers, aiming to evaluate the incidence and the risk factors of HCC and variceal bleeding development. Hepatocellular carcinoma (HCC) remains the most important life-threatening complication of HCV cirrhosis. IFN significantly reduced the risk of HCC in this category of patients; however, usage was limited by contraindications (depression, immune diseases). The development of new DAAs surpassed these limitations imposed by IFN usage. The risk of HCC associated with DAA therapy remains unclear. Several studies found that DAAs increased the risk of HCC recurrence (19, 20). These studies investigated HCC recurrence and not incidence, had a limited follow-up period and were underpowered. An extensive retrospective study included more than 3,000 HCV cirrhotic patients treated with either IFN or DAAs or a combination. During a 6.1-year follow-up period, DAA treatments reduced the risk of HCC up to 71%, with no difference between IFN and DAAs (9).

The most important risk factors associated with HCC in HCV cirrhotic patients were age, gender, excessive alcohol consumption, comorbidities (diabetes, obesity, renal diseases, lymphoma, HIV coinfection) (21).

Our study investigated the risk of HCC development in young (<60 years) and elderly (≥60 years) patient groups. During the 18-month follow-up period only 3.7% of cases developed HCC. The *male : female ratio* of HCC incidence was 2.5:1; however, the difference was not statistically significant, likely due to the relatively small sample size.

To overcome the bias due to differences in the distribution of covariates among young and elderly patients treated with PrOD, we created one-to-one matches using propensity score analysis. The model was used to obtain a one-to-one match according to the nearest neighbor matching method, resulting in a sample size of 230 patients per cohort.

The propensity score matching analysis showed an increased probability of HCC development in the elderly patients (5.3%) compared to the young patients (1.8%). The lack of statistical significance may be due to the higher number of females in the elderly patient group. Alpha-fetoprotein is considered an important risk factor for HCC in cirrhotic patients irrespective of cause (22). Long-term follow-up studies have found that approximately 1-8% of patients with cirrhosis develop HCC per year, 2% in HBV-infected cirrhotic patients and 3-8% in HCV-infected cirrhotic patients (23). We found a significant correlation between AFP values and the incidence of HCC (64% of HCC cases were noted in patients with a baseline AFP of more than 7

ng/mL). Edge of decompensation had a significant influence on HCC development.

The second most common cause of death in cirrhotic patients is gastrointestinal bleeding produced by esophageal varices effraction (24).

IFN prevented or delayed the development of de novo esophageal varices; however, its efficacy against gastrointestinal bleeding was not established (25). There was a lack of information regarding effectiveness of DAAs in prevention of variceal bleeding.

In Romania between 2015-2016, a single oral antiviral medication was available for the treatment of HCV, and National Insurance House reimbursement conditions were limited to patients with compensated liver cirrhosis (Child-Pugh class A) (26). The limiting condition for PrOD treatment was related to the demonstration of F4 fibrosis by FibroMax™ or liver biopsy. The majority of patients were evaluated by FibroMax™, and we included only patients with a value of over 0.75, considered a cut-off for an F4 METAVIR score. Patients who were at the limit of F4 on the FibroMax™ examination usually had hepatic stiffness values evaluated with Fibroscan in the clear liver cirrhosis spectrum. Using the FibroMax™ method permitted the inclusion of a population of patients with cirrhosis, sometimes at the edge of decompensation. In this case, the mean value of Fibroscan is above the limit that the Baveno VI (13) consensus considers indicative of clinically significant portal hypertension.

Furthermore, some patients already had esophageal varices (included in the Baveno II stage), some had platelet counts indicating portal hypertension or albumin values indicating a deficiency in liver albumin synthesis. The cohort of patients approved for PrOD treatment due to compensated status as defined by Child-Pugh scores allowed the admission of a wide spectrum of stages of liver cirrhosis into the study. Considering the grading of patients after FibroMax™ and Fibroscan, and adopting the proposed Baveno staging (13), we found that we treated compensated liver cirrhosis patients in a lower proportion than those at the limit of edge of decompensation.

In cirrhotic patients without varices, the rate of developing them was estimated at 5-8% per year (13, 27). Patients with small varices develop large varices at an annual rate of 8% as well (27). The risk of first variceal bleeding is higher in patients with larger varices, with red-signs and decompensated liver cirrhosis, and range between 6-15% per year (28). In our study the annual rate of the first variceal bleeding in patients who already had esophageal varices was 2.65% per year, with no significant difference between the elderly and the young group (p=0.918). No patient without previous described varices had any bleeding. The lower percentage of variceal bleeding after SVR than reported data from literature and the fact that none of patients without esophageal varices developed bleeding could suggest a tendency of improving portal hypertension after SVR and the risk of bleeding which, however, is not eliminated.

Our study has some strengths such as large number of patients, homogeneous groups of cirrhotic genotypes 1b cases, a high proportion at edge of decompensation and excellent adherence. However, the main limitation is due to short period of follow-up.

CONCLUSIONS

The risk of HCC (5.3%) and the vari-

ceal bleeding (2.0%) in elderly patients following viral eradication by IFN-free DAA therapy may follow a specific pattern, comprised of factors like the edge of decompensation, AFP levels, age, esophageal varices.

However, further larger cohort studies with longer follow-up are needed to characterize this pattern.

CONFLICT OF INTERESTS AND FUNDING

The authors declare that there is no conflict of interest and they received no specific funding regarding this scientific research.

NEWS

COVID-19: EVEN THROUGH DEATH WE ARE NO LONGER EQUAL?

A recent research paper entitled *"Racial disparities in COVID-19 mortality are driven by unequal infection risks"* made by a group of researchers led by *Jon Zelner*, after analyzing COVID-19 incidence and mortality data in the state of Michigan, signals a surprising paradigm shift: the unequal distribution of the risks of infection between different race- ethnic groups. The black population was the most affected group of all, with an age-standardized incidence of 1,626/ 100,000 and a mortality rate of 244/100,000. Using Hierarchical models of Bayesian regression for the data analysis and the posterior predictive controls for the results validations, dramatic disparities were found, the age-standardized incidence being 5.5 (95% CrI= 5.4, 5.6) and the mortality 6.7 (95% CrI= 6.4, 7.1) times higher for the Blacks, compared with the Whites. Zelner J, Trangucci R, Naraharisetti R, *et al.* Racial disparities in COVID-19 mortality are driven by unequal infection risks. *Clin Infect Dis* 2020. doi: 10.1093/cid/ciaa1723).

CATARACT SURGERY IN PATIENTS WITH HISTORY OF UVEITIS- MEDIUM TERM FUNCTIONAL OUTCOMES (Abstract). **Aim**: Evaluating the functional outcomes in patients with history of uveitis who previously underwent cataract surgery during 2009-2019, analysis of the best postoperative visual acuity and IOP after first day, one month, 3 months and last postoperative. **Material and methods:** Comparative/retrospective study which included cataract surgery patients with a history of uveitis evaluated between January 2009 and December 2019 in Iaşi, Department of Ophthalmology, "Sf. Spiridon" County Clinical Emergency Hospital. The study included a number of 102 eyes divided into two groups: 59 eyes from 51 patients (25 women and 26 men) the cataract and uveitis group (study group) and 43 cataract eyes (control group). All patients had cataract surgery performed by phacoemulsification and IOL-PC implantation, while the pre- and postoperative evaluation was performed according to a standardized protocol. The database was built in the *EXCEL* program and was statistically processed with the *SPSS 18.0* program. Postoperative follow-up was performed at 1 day, 1 month, 3 months and last postoperative follow up (six month). **Results:** The average age of patients of the 2 groups was 65 years. In all cases, preoperative topical steroid anti-inflammatory treatment was administered for 1 week and postoperatively, for 6 weeks. General anti-inflammatory steroids (CSR) were administered preoperatively and postoperatively in 9 patients with intermediate or posterior uveitis for 8 weeks. In two cases a capsular tension ring was used to stabilize the bag. One case required ECCE + placement of IOL in the sulcus. Only one case required IOL explantation due to severe inflammation. Among the postoperative complications, the inflammatory glaucoma and recurrent uveitis predominated. **Conclusions:** Cataract surgery with IOL implantation resulted in improved postoperative visual acuity in patients with cataract and uveitis, which was maintained at the last follow-up. In the immediate postoperative period, both groups had similar functional results. **Keywords:** CATARACT SURGERY, UVEITIS, PHACOEMULSIFICATION, CYSTOID MACULAR EDEMA, INTRAOCULAR IMPLANT.

Cataract is a major cause of vision loss in patients with uveitis, up to 40% of cases being mainly due to cataracts. Frequent complication of uveitis occurs on the one

hand due to inflammation but also due to chronic treatment with corticosteroids (CSR). The incidence of cataracts in uveitis varies from 57% in pars planitis to 78% in Fuchs' heterochromic iridocyclitis. Cataract surgery in uveitic eyes is difficult and can have many unexpected intraoperative complications. This represents a challenge for the surgeon due to the particular existing situations, namely: small pupils, posterior iris synechiae, the presence of pupillary membranes, fibrous anterior capsule (1, 2). Until the advent of corticosteroids in the early 1960s, eye inflammation was often impossible to be controlled, and articles discussing the results of cataract extraction in swollen eyes reported a high incidence of severe complications (3). In many cases, complications resulted in marked reduction of vision or even loss of the eye. Amit K Reddy *et al.* in a study that included 3,013 eyes from 2,019 patients, found a low incidence (2%) of persistent postoperative uveitis, a 29% incidence of postoperative macular edema and no case of severe granulomatous uveitis. In general, postoperative uveitis is due to the presence of inflammation at the time of surgery, cortical debris after cataract surgery and intraoperative manipulation of the iris (retractors, stretching, sphincterotomies (4). More recent publications have reported a considerable decrease in the incidence of intraoperative and postoperative complications during cataract extraction in patients with uveitis. On the one hand, this is due to a very good control of preoperative inflammation and on the other hand, to the evolution of microsurgical techniques in recent years (4, 5, 6).

MATERIALS AND METHODS

It is a retrospective study that included cataract patients with a history of uveitis evaluated between January 2009 and December 2019 in the Department of Ophthalmology, from "Sf. Spiridon" County Clinical Emergency Hospital, Iasi. The study included a number of 102 eyes divided into two groups: 59 eyes from 51 patients (25 women and 26 men) the cataract and uveitis group (study group) and 43 cataract eyes (control group). Inclusion criteria for the study group were patients with uveitis who underwent cataract surgery. Presence of uveitis had to be confirmed prior surgery. There had to be at least three months with no inflammation in the absence of treatment before cataract surgery. Exclusion criteria: absence of associated uveitis; eyes with active inflammation or under corticosteroid treatment. Patients scheduled for cataract surgery had their surgery planned in advance. The surgery was performed under topical or parabulbar anesthesia. All patients underwent cataract surgery by phacoemulsification and IOL-PC implantation, the pre- and postoperative evaluation was performed according to a standardized protocol. In all cases, in the uveitis group, topical steroid and non-steroidal anti-inflammatory drugs (NSAIDs) were administered preoperative for 1 week and postoperative for 6 weeks; in some selected cases systemic anti-inflammatory corticosteroids were administered. Postoperative follow-up was performed at 1 day, 1 month, 3 months and last control after cataract surgery. The visual acuity was measured with the Snellen optotype, and the IOP was measured by Goldmann applanation tonometry (GAT); slit lamp evaluation of the anterior segment and posterior segment with the Volk 78D lens were also performed; OCT examinations were performed at Oftaprof Clinic

using Zeiss Cirrus HD-OCT to detect cystoid macular edema (CME).

Ethical Approval

During the study, the principles of the Helsinki Declaration were observed. Patients have signed an informed consent, which was attached to the observation sheets.

Statistical Analysis

The database was created in the *EXCEL* program and was statistically processed with the *SPSS 18.0* software.

RESULTS

102 eyes were divided into two groups: the study group (59 eyes from 51 patients) with cataract and uveitis and the control group (43 eyes) with cataract only.

Distribution of patients by study groups. Statistical analysis by age groups highlights the following aspects :

The mean age of patients with cataracts and uveitis (group I) was significantly lower than that of patients with cataracts alone (group II) (57.31 *vs.* 70.12 years).

- the highest frequency of patients with cataract and uveitis is found in the 60-69 age group (25.4%) and 70-79 years (41.9%)

- the incidence peak is noted in the 60-69 years (25.4%) in patients with cataract;

The average age of patients was 57.31 ± 16.30 years in those with uveitis and 70.11 +/- 11.37 in the control group, average of the groups being 65 years (fig. 1). In all cases, in the uveitis group, topical steroid anti-inflammatory and non-steroidal anti-inflammatory drugs (NSAID) were administered preoperative for 1 week and postoperative for 6 weeks, respectively. Systemic anti-inflammatory corticosteroids were administered preoperative and postoperative in 9 patients with intermediate or posterior uveitis for 8 weeks. In most cases the IOL was positioned in the capsular bag. In two cases capsular tension rings were used to stabilize the bag. One case required extracapsular extraction + placement of IOL in the sulcus. Phaco-trabeculectomy combined surgery was performed in 2 eyes. Only one case required IOL explantation due to severe inflammation. The maneuvers performed in case of intraoperative complications were: synechiolysis (in 17 eyes, 50.8%), tension ring implantation (2 eyes), small pupil requiring iris retractors, intracameral phenylephrine (mezatone) (14 eyes) and anterior vitrectomy (2 eyes) (fig. 2, tab. I). Posterior segment complications included: recurrent uveitis (23 eyes, 39%) at 3 months, inflammatory glaucoma (6 eyes, 11.9%) at 1 year, cystoid macular edema (4 eyes, 11.9%) at 6 months and opacification of the posterior capsule (4 eyes, 10.2%) at one year (fig. 3, tab. II).

In the first study group most uveitis was idiopathic (80%), followed by ankylosing spondylitis in proportion of 7.5% and other etiologies in smaller and equal proportions (sarcoidosis, TB, juvenile idiopathic arthritis, Fuchs' heterochromic iridocyclitis, etc.) (fig. 4).

In the first group (cataracts and uveitis) visual acuity varied preoperatively from 0.005 to 0.50; while at the last follow up the visual acuity ranged from 0.004 to 1.0. The mean level increased significantly at 1 day postoperatively by 145% ($p = 0.001$) and still by approximately 34% at 1 month postoperatively ($p = 0.001$). Patients gained on average 3 lines of visual acuity (fig. 5.) The mean intraocular pressure was 15.97 +/- 4.6 mmHg (SD) preoperatively, on the first postoperative day it was 16.8 +/- 5.02 mmHg (SD), and 16.12 +/- 3.89 mmHg (SD) at one month. IOP decreases at 1

month postoperatively by 4% (p = 0.520) and after 3 months the decrease in intraocular pressure from one moment to another was by about 8% (p = 0.146). The IOP changes were not statistically significant (fig. 6). In patients treated with topical steroids, the mean level of postoperative visual acuity was slightly lower (0.37 *vs.* 0.45; p = 0.477), while postoperative IOP was slightly higher (15.58 *vs.* 14.43; p = 0.526). The correlation between postoperative visual acuity and the number of anti-inflammatory drugs was direct, reduced in intensity (r = +0.196; p = 0.138), but statistically insignificant. Severity of postoperative inflammation obviously leads to the use of a higher number of anti-inflammatory drugs (postoperative visual acuity and the period of administration of anti-inflammatory drugs were apparently parametrically independent r = +0.094; p = 0.477).

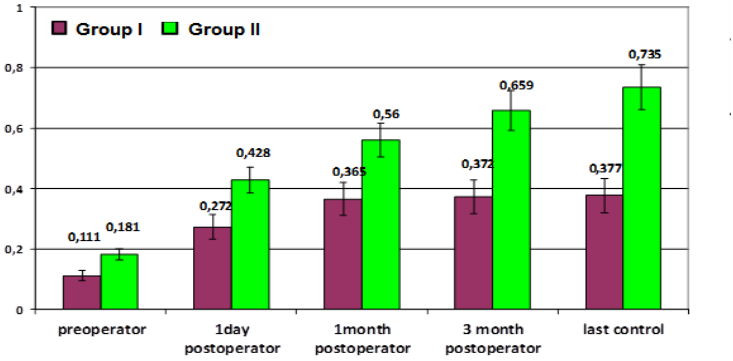

Fig. 5. Evolution of the mean level of visual acuity on study groups
The last control period (six month)

In the cataract control group, visual acuity varied preoperatively from 0.004 to 0.50; whereas at the last follow up, this ranged from 0.10 to 1.0, being significantly higher than that recorded in patients with uveitis (p = 0.001). The average level of visual acuity increased significantly at 1 day postoperatively by 136% (p = 0.001), an approximately extra 31% at 1 month postoperatively (p = 0.001), while after 3 months the visual acuity increased from one follow-up to another by 11-18% (p <0.001). Patients gained on average 5 lines of visual acuity (fig. 6). There is a statistically significant difference in final postoperative visual acuity between the two groups (p = <0.001).

The mean intraocular pressure was 15.88 +/- 3.68 mmHg (SD) preoperatively, the first postoperative day was 16.44 +/- 3.49 mmHg (SD), and at 1 month it was 15.05 +/- 3.49 mmHg (SD) (p <0.039) (fig. 6).

In all cases, in the uveitis group, topical steroid and non-steroidal anti-inflammatory drugs (NSAIDs) were administered preoperative for 1 week and postoperative for 6 weeks, in some selected cases systemic anti-inflammatory corticosteroids were administered.

There was no correlation in the uveitis cases between visual acuity and inflammation-free time interval (fig. 7).

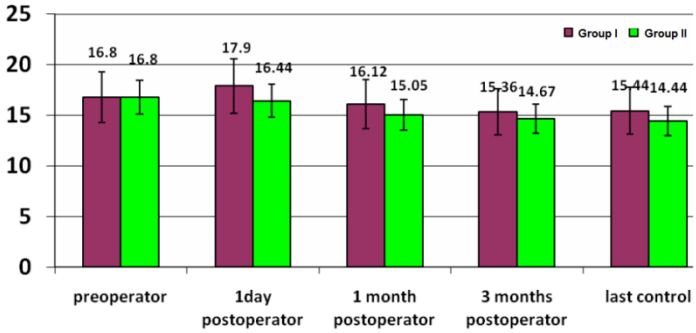

Fig. 6. Evolution of the mean level of intraocular pressure on study groups

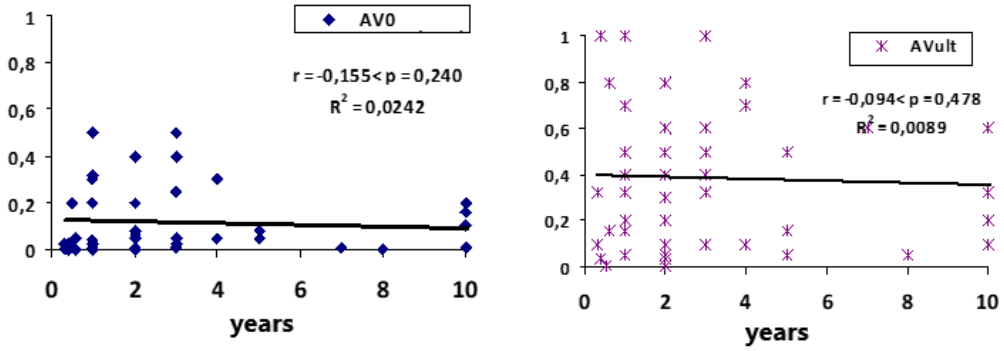

Fig. 7. Visual acuity and inflammation-free time interval correlation

There was no statistical significance between IOP and inflammation-free time interval (fig. 8).

In patients with synechiolysis, visual acuity significantly increased from 0.14 to 0.33 (p = 0.05), and intraocular pressure dropped significantly from 18.2 to 14.9 mmHg (p = 0.05). In patients with recurrent uveitis, visual acuity increased significantly from 0.09 to 0.33 (p = 0.05), and intraocular pressure dropped slightly from 17.3 to 16.65 mmHg (p = 0.623) (fig. 9).

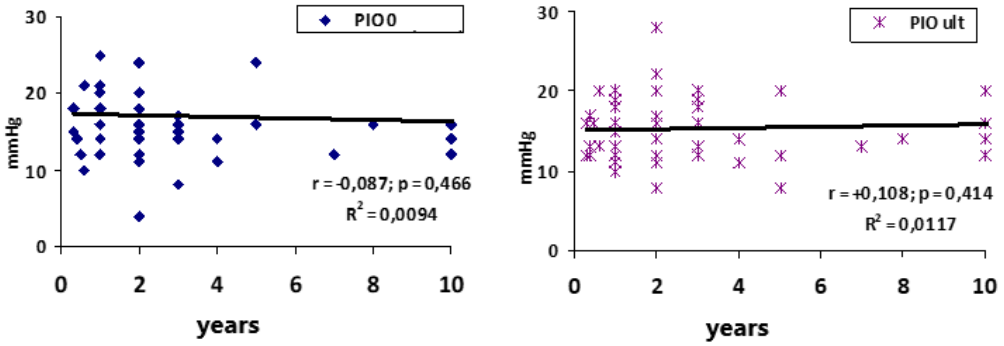

Fig. 8. IOP and inflammation-free time interval correlation

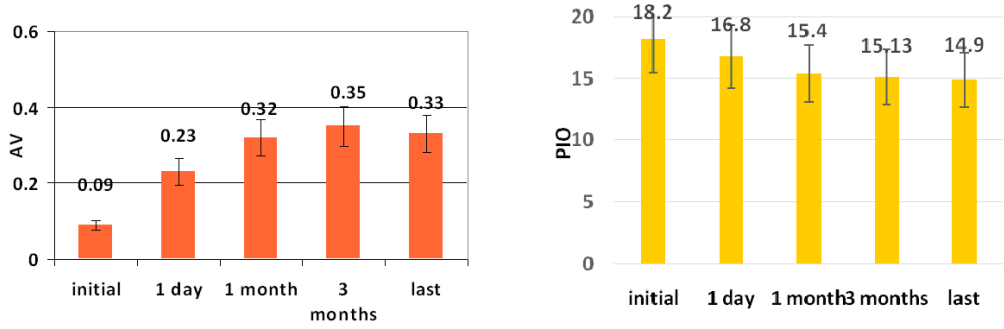

Fig. 9. Functional results of patients with recurrent uveitis

Logistic regression (multivariate analysis) provides a useful means to highlight the relationship between a presumed dependent variable and one or more explanatory variables called “predictors” which can be categorical or continuous. Risk is mathematically modeled as an equation as a collection of predictor variables. Linear regression models showed that visual acuity was significantly determined, in general, by gender, age, preoperative visual acuity - model 3 (y = 0.347 - 0.095 sex + 0.001 age + 0.924 AV0; p = 0.029), but model 5 also highlights the influence of the preoperative IOP and the interval from subsidence of inflammation as parameters that influence the visual acuity result at the last evaluation (y = 0.492 - 0.081 sex +0.001 age +0.914 AV0 - 0.07 PIO0 - 0.002 interval; p = 0.016). Of the preoperative factors, only gender is a good predictor of synechiolysis (AUC = 0.644; 95% CI: 0.501-0.786). Of

the preoperative factors, age (AUC = 0.659; 95% CI: 0.508-0.809) and the interval from extinction of the uveitis (AUC = 0.678; 95% CI: 0.534-0.821) seem to be good predictors of recurrent uveitis determinism (fig. 10).

Multivariate analysis revealed that a greater number of anti-inflammatory drugs administered for a significantly longer period can change the postoperative visual acuity (y = 0.709 + 0.646 AIN number - 0.274 Per Adm; p = 0.042) and postoperative IOP (y = 19.42 + 0.431 AIN number - 0.786 Per Adm; p = 0.008).

DISCUSSION

Cataracts are a common complication of uveitis, which occurs on one hand due to inflammation but also due to chronic treatment with corticosteroids. Cataract surgery in patients with uveitis is a serious challenge for the anterior segment surgeon. Today, phacoemulsification with intraocular lens implantation (IOL) in the capsular bag is the care standard for most patients with uveitis. However, despite the remarkable advances in surgical techniques and IOL materials, certain specific considerations should be made in terms of patient selection, preoperative preparation, as well as preoperative and postoperative management for long-term successful outcomes (7, 8). Studies show that there is a number of peculiarities regarding surgery of patients with uveitis, which determine the reduction of inflammation in the postoperative period: minimum number of maneuvers during surgery, short duration of surgery, small instead of large incisions, phacoemulsification with IOL implantation instead of extracapsular extraction of the lens and so on.

Preoperative management depends on the type and etiology of the uveitis, uveitis activity, the absence or presence of preoperative CME - there is no consensus of experts, several protocols being available (5, 6, 9). Thus, in non-granulomatous anterior uveitis Prednisolone acetate 1% eyedrops are administered 4 times/day 3-7 days preoperatively and in anterior uveitis associated with IJA (idiopathic juvenile

arthritis), severe granulomatous, intermediate or posterior uveitis, prednisone is recommended with dosage of 1mg/ kg bw/day, 3 days preoperatively. Also, in all cases, nonsteroidal anti-inflammatory drugs (NSAID) eyedrops 4 times/day 3-7 days before surgery, are proved to be more efficient in preventing the development of cystoid macular edema.

Postoperatively corticosteroid and antibiotic eyedrops are administered, NSAID eyedrops are continued 4 times/day for 6-8 weeks, up to 6 months depending on the case; in severe forms it is continued, tapering the treatment with Prednisone up to a minimum dose of 10 mg/day and combination of cycloplegic-mydriatic eyedrops (tropicamide 1% and phenylephrine 5%) 4times/day 5-7 days (6, 8, 9, 10, 11). Studies show an incidence of only 4% of CME in patients receiving oral and postoperative corticosteroids versus 27% in those without treatment (10, 12). Idan Hecht *et al.* exemplified in a study of 13,368 patients with a mean age of 73 years, who underwent cataract surgery, treated only with corticosteroids, only with NSAIDs or combination of the two, that postoperative treatment with steroids among patients undergoing treatment for uncomplicated cataract surgery was associated with lower rates of opacification of the posterior capsules compared with NSAID-only treatment (10).

The presence of inflammatory glaucoma should be established before surgery and anti-glaucoma therapy (avoiding prostaglandin derivatives) should be initiated. In the case of herpetic uveitis, prophylactic antiviral therapy with acyclovir or valaciclovir should be given at least 1 week before surgery to prevent recurrent viral infection (5, 8). Functional outcomes may be influenced by immediate and late postoperative complications: CME with an increased incidence after ECCE (33-66%) *vs.* Phaco (12-59%); severe anterior segment inflammation (posterior synechia, pupillary membranes); postoperative IOP increase - anti-glaucoma medication + corticosteroids; Posterior Capsule Opacification (PCO) (23-48% at 1 year) - the most common with variable incidence in different studies - requiring Nd: Yag capsulotomy - are prevented through postoperative inflammation control, well-centered circular capsulorhexis, square edge design of the IOL, meticulous removal of OVDs, etc. (5, 8, 10, 11, 13).

In our study, similarly to other literature studies, postoperative visual acuity increased significantly and was maintained at the last follow up. Sonia Mehta and colleagues in a review of literature using a database of 89 articles found that patients with a history of uveitis but no inflammation before surgery had a visual acuity of 20/40 or better in 69% cases especially if cataract surgery was performed through phacoemulsification (2). However, the presence of active uveitis at the time of phacoemulsification was associated with poor visual results (2, 13). In our study, the most frequent postoperative complication was recurrent uveitis (39%), which occurred on average at 3 months, 6 months and the latest at 2 years postoperatively. Most often this was due to intraoperative maneuvers at the pupillary level (stretching, synechiolysis, etc.).

The incidence of CME was 11% in cases with complicated surgery, intermediate or posterior uveitis and prior history of CME. Marie-Lyne Belair and co-workers evaluated the incidence of cystoid macular edema in two groups of patients who underwent cataract surgery, one that associates uveitis (41 eyes) *vs.* the one without

associated uveitis (52 eyes), similar to our study finding an 8% incidence of edema in those with uveitis and its absence in those without. In those treated with preoperative and postoperative corticosteroids the risk of edema was very low (14). In general, PCO occurred at 8 months - 2 years postoperatively, with an incidence of 10%. In a retrospective study of 3,013 eyes Amit K. Reddy evaluated the incidence of persistent anterior uveitis after cataract surgery, which was found in 2% while cystoid macular edema appeared in 29.4% of cases. Regardless of race (Caucasian or African American), uveitis persisted at one year postoperatively, despite moxifloxacin and topical corticosteroid therapy, periocular and intravitreal dexamethasone implant placement. A small percentage showed opacification of the posterior capsule. Visual acuity increased postoperatively in the study group similar to the control group, in accordance with low intraoperative and postoperative complications, as well as prompt treatment with pre- and postoperative anti-inflammatory depending on the cause of ocular inflammation (4). In a study on 111,641 eyes, of which 1,173 with associated uveitis, which underwent cataract surgery, Colin J Chu *et al.* found poorer visual acuity in the uveitis group postoperatively on the first day and at 12-24 weeks and increased intraocular pressure at the same intervals as opposed to the group without uveitis, with an increased frequency of anti-glaucoma procedures (7). In our study in the immediate postoperative period (one day) both groups had almost similar functional results; after one month the functional results in the control group are much better, with statistically significant differences between groups. The presence of a high percentage of recurrent postoperative uveitis (39%) in the study group would be an explanation of the weaker functional outcomes in this group compared to the control group. Preoperative inflammation control and the correct treatment of pre-operative CME can lead to good functional results after surgery. The reached data are comparable to those in the literature. Currently there are no studies comparing the level of visual acuity and intraocular pressure in patients with inflammation *vs.* non-inflammation who have undergone the same type of surgery. Thus, cataract surgery in eyes with uveitis can result in normal or near-normal visual acuity in most cases, at least in the short term, although it is not so common with regard to age-related (non-uveitic) cataracts. Further research is needed on a significant number of patients, in order to increase the level of confidence on which we can make decisions regarding the surgical treatment of cataract in uveitic eyes, and in particular to develop evidence that is specific to the individual clinical entities that make up this heterogeneous group of disease.

The limits of the study consist in the retrospective nature, the small number of enrolled cases and, most importantly, lack of uniformity of the evaluation period from surgery to the last follow-up. The absence of visual acuity results and intraocular pressure at longer intervals postoperatively also represents a serious limitation, and the results cannot be extrapolated to the general population.

CONCLUSIONS

Cataract surgery with artificial lens implantation resulted in improved postoperative visual acuity in patients with cataract and uveitis, which was maintained at the last follow up. In the immediate postopera-

tive period, both groups had similar functional results. Preoperative and postoperative inflammation control was a key factor in achieving relevant functional results. There is a statistically significant difference in final postoperative visual acuity between the two groups. Cataract surgery in uveitis patients requires careful evaluation of the diagnosis to determine the cause of uveitis, adequate patient selection, zero tolerance to preoperative inflammation, vigilant use of drugs to control preoperative inflammation, meticulous surgery, correct decision for implantation of IOL, control of postoperative inflammation and early detection and aggressive management of complications.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

ASSOCIATION BETWEEN DIABETES MELLITUS AND SARS-COV2 INFECTION - A RETROSPECTIVE STUDY IN THE PULMONOLOGY CLINIC OF TÂRGU MUREȘ (Abstract): The aim of our study was to establish the relationship between diabetes mellitus (DM) and SARS-CoV-2 infection, given that DM patients have an increased risk of developing severe infections/complications. **Material and methods:** The study included 108 (33.4%) patients with known or unknown DM or prediabetes PD (fasting blood glucose 100-126 mg%) from a group of 323 COVID-19 patients. Age distribution in the first group with DM/PD: 15.7% ≤ 40 years old, 27.7% 41-60 years old, 52.7% 61-80 years old, 3.7% > 80 years old. **Results**: We noted a higher percentage in the age group 61-80 and > 80 years old in nondiabetic patients. 92 (85.16%) from the first group and 174 (80.9%) in the second group also associated obesity/overweight. DM/PD were not previously known in 33.4%. 40% required either introduction of insulin or increased doses, due to marked imbalances. Severity of COVID-19 was higher in the DM: 17.6% *vs.* 53.4% mild forms, 37% *vs.* 27.9% moderate pneumonias, 45.3% *vs.* 18.6% severe forms (CT: multiple bilateral "ground glass" infiltrates or consolidation; respiratory failure) with extrapulmonary complications. Fatality was 12% in the first group and 7.4% in the nondiabetic group. All patients associated increased inflammatory markers (CRP, LDH, ferritin) and lymphopenia. **Conclusions:** DM was an important risk factor for high severity and fatality of infection even in middle-aged people while SARS-CoV-2 infection determined an imbalanced DM and clinical *de novo* DM/PD. Obesity was a major risk factor for SARS-CoV-2 in both groups (with or without DM). The recommendation of close monitoring after discharge is part of a personalized management to prevent further unfavorable evolution and post COVID-19 complications.
Keywords: DIABETES MELLITUS, PREDIABETES, SARS-CoV-2 INFECTION.

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the novel coronavirus identified in December 2019 in Wuhan, China, causes the coronavirus

disease (COVID-19), that spread rapidly worldwide and had been declared a pandemic by the World Health Organization (WHO) in March 2020 (1, 2).

SARS-CoV-2 is part of the *Coronaviridae* family and is a positive-stranded RNA virus, surrounded by a protein-decorated lipid bilayer containing a single-stranded RNA genome. The main entry receptors for SARS-CoV2 in human cells are angiotensin-converting enzyme 2 (ACE2) and dipeptidyl peptidase-4 (DPP4), highly expressed in the vascular endothelium, pericytes, lung alveolar epithelial cells (type II pneumocytes), cardiac cells, macrophages, pancreatic islets and enterocytes of the small intestine (1, 3, 4, 5).

Greater risk factors in developing severe COVID-19 with ICU admission or death include advanced age, male sex, cardiovascular diseases (CVD), obesity, type 1 diabetes mellitus (T1DM) or type 2 DM (T2DM), renal chronic diseases, tumors, leukemia, lymphoma or myeloma, immunocompromised states after organ transplants, immunotherapy, chemotherapy, smoking, pregnancy, sickle cell disease, splenectomy, Down syndrome (6).

DM is a complex clinical syndrome, characterized by chronic hyperglycemia due to defects in insulin production, action or both. Besides the classical complications: a) acute (hypoglycemia, ketoacidosis, ketonic coma) and b). chronic (atherosclerosis with increased risk of coronary heart disease, stroke, peripheral arteriopathy, hypertension, retinopathy, nephropathy, neuropathy), DM is associated with a higher susceptibility in developing bacterial, parasitic or viral infections (7, 8, 9). These complications can shorten survival (in 2016 WHO cited 1.6 million deaths directly linked to DM and other 2.2 million that were caused by hyperglycemia) (10) .

The presence of DM and the individual condition of hyperglycemia seem to be directly involved with COVID-19 severity and increased mortality, highlighting the importance of shared disease pathophysiology for therapeutic approaches (11).

MATERIAL AND METHODS

We analyzed the particularities of the association between diabetes mellitus (DM) and SARS-CoV-2 infection in patients hospitalized in the Pulmonology Clinic of Târgu Mureș, Romania.

The study included 323 patients with SARS-CoV-2 infection confirmed in all cases by real time Reverse Transcriptase Polymerase Chain Reaction (RT PCR). The patients were included in the study as they were admitted in the Pulmonology Clinic of Târgu Mureș, Romania, during November - December 2020.

Inclusion criteria for the group 1: patients with SARS-COV2 infection and DM or prediabetes PD (previously documented or at first diagnostic) (108 patients). Prediabetes was defined as the situation in that the patients had fasting blood glucose between 100-126 mg%.

Inclusion criteria for the group 2 (control): patients with SARS-CoV-2 infection without DM or PD (as medical history or during the hospitalization in the Pulmonology Clinic Targu Mureș caused by SARS-CoV-2 infection) (215 patients).

The information recorded from each case file were individual data (gender, age, body mass index BMI, symptoms, medical history), laboratory tests: glucose levels, hemoleucogram, inflammatory markers: C reactive protein (CRP), lactate dehydrogenase (LDH), fibrinogen, ferritin; severity of COVID-19 pneumonia, treatment, as

well as evolution and outcome.

The diagnosis of COVID-19 was based on clinical evaluation and specific investigation RT-PCR and thoracic imaging – Computed tomography CT with intravenous contrast or chest X-Ray.

The aim of our study was to analyze the association between DM/PD and SARS-COV2 infection, the severity of associated diseases, comorbidities and fatality rate in patients hospitalized in the Pulmonology Clinic of Târgu Mureș, Romania. We made some comparisons between the group of patients with DM or PD and the group of patients without DM and PD.

We reviewed some national and international data considering the SARS-CoV-2 infection and association with DM and other comorbidities.

RESULTS

In our study, from 323 patients hospitalized with COVID-19 pneumonia (randomly chosen), 108 patients 33.4% (group 1) were found with DM or PD, indicating that DM and PD are major risks factors for the SARS-CoV-2 infection. We made comparisons with the group 2 (215 patients without DM or PD). The group 1 included 55 men and 53 women, and the male/female ratio was 1.03. The group 2 has a similar male/female ratio 1.05 (109/106).

We noted 3 patients with Type1 DM and in the rest of the group 83 had T2DM and 22 PD. A high number - 37 patients (34.2%) were not known with a previous history of DM or PD. Fasting blood sugar was taken several times for each patient in the morning and 4 time during the day ("glycemic profile") in medium/severe forms and in unbalanced DM).

The age distribution in the first group ranged in all age groups: from 35 to 40-year-old 17 patients (15.7%), 41-60-year-old 30 patients (27.7%), 61–80-year-old 57 patients (52.7%), to > 80-year-old 4 patients (3.7%). A higher prevalence of DM and PD was noticed in the years old Ung/middle age in our study group, 43.4% were between 35-60 years-old, comparing with 35% found in the literature (12). The mean age in our first group was 62-year-old. One possible explanation is that SARS-CoV2 infection in Romania affected more the middle-aged people (the mean age in Romania was 48-year-old in November 2020) (13). Other explanation could be the fragility of diabetic patients against SARS-CoV-2 infection in middle-aged people.

The age allocation in the second group was: 35 - 40-year-old 19 patients (8.83%), 41–60-year-old 42 patients (19.5%), 61–80-year-old 133 patients (61.9%), > 80 years 21 patients (9.76%). We note a higher percentage in patients from the age group 61-80 and > 80-year-old in nondiabetic patients. 92 patients (85.16%) from the DM/PD group also associated obesity or overweight (17 morbid obesity, 36 degree II of obesity, 24 degree I of obesity, 15 overweight) especially in women (tabs. I, IV). At the same time the second group without DM/PD met also high levels of obesity and overweight emphasizing that obesity is a major risk factor for SARS-CoV-2 infection (tab. III)

There were no differences between the prevalence of obesity and overweight in the subgroup with DM and PD, but both have high values. This aspect indicating on one hand the high-risk factor that obesity offers for DM and PD and on the other hand the strong necessity for population weight control. We discovered multiple associated other diseases in both study groups (tab. I).

TABLE I

Obesity and overweight in the DM/PD group

	DM patients (86)	PD patients (22)	Total
Obesity	40 - 46.5%	7 - 31.8%	47/108 - 43.5%
Overweight	37 - 43%	8 - 36,4%	45/108 - 41.66
Total	77/86 - 89.5%	15/22 - 68.2%	92/108 - 85.16%

TABLE II

Comorbidities in the DM/PD group

	DM patients (86)	PD patients (22)	Total group 1 (108 patients)
Coronary heart disease CHD	21	19	40 - 37.0%
Hypertension	27	24	51 - 47.2%
COPD	11	8	19 - 17.6%
Asthma	5	7	12 - 11.1%
Previous renal diseases	7	2	9 - 8.3%

TABLE III

Comparison between comorbidities repartition in the 2 groups of study

	Group 1 DM and PD (108 patients)	Group 2 without DM/PD (215 patients)
Obesity	47 - 43.5%	99 - 46%
Overweight	45 - 41.66%	75 - 34.8%
Coronary heart disease CHD	40 - 37.0%	69 -32%
Hypertension	51 - 47.2%	96 - 44,6%
Chronic Obstructive Pulmonary Disease	19 - 17.6%	33 - 15.3%
Asthma	12 - 11.1%	22 - 10.2%
Previous renal diseases	9 - 8.3%	12 -5.5%
Tumors or immunodepresive treatment	9 - 8.3%	11 - 5.1%

Coronary heart disease (CHD) and hypertension (HTN) were very frequent 37%, respectively 47.2% in the first group (tabs. II, III). This association could at least partially contribute to the higher percentage of DM/PD in SARS-CoV-2 infection, together with some specific susceptibility to SARS-CoV-2 of the patients with DM. In the second group CHD was discover in 32% and HTN 44% of patients.

If we compare case distribution based on gender and nutrition dysfunction, we can observe a higher prevalence of obesity and overweight in women in both groups (tab. IV).

TABLE IV

Association of DM and PD and obesity/overweight to SARS -CoV-2 patients

	Males with DM or PD (55)	Females with DM or PD (53)	Males in group 2 (109)	Females in group 2 (106)
Morbid Obesity	10	7	11	8
Grade II Obesity	16	20	12	20
Grade I Obesity	11	13	19	29
Overweight	6	9	36	39
Total	43 - 78.1%	49 - 92.4%	78 - 71.5%	96 - 90.5%
	92 - 85.16%		174 - 80.9%	

Regarding the severity of COVID-19 cases in the DM/PD group: 19 patients (17.6%) had mild forms, 40 (37%) had moderate pneumonias, 49 (45.3%) were severe cases (CT with multiple bilateral infiltrates in "ground glass" or consolidation, respiratory failure, long evolution ICU admission or death). 21 patients needed ICU admission. There were 13 deaths (12%) in the first group and 16 (7.4%).

Severity of COVID-19 was also extremely high in the nondiabetic patients but lower than first group with DM: 60 patients (27.9%) had mild forms, 115 (53.4%) had moderate pneumonias, 40 (18.6%) were severe cases.

Because patients with extreme inflammation, the so-called "cytokine storm" were considered at great risk for severe COVID-19 disease, including bigger pancreatic inflammation and possible unbalance of the glycemic values (14), we performed a periodically determination of some biomarkers to assess the hyperinflammation (e.g., ferritin, high-sensitivity C-reactive protein, lactate dehydrogenase, hemogram showing lymphopenia). At the same time, analyzing the importance of pro-inflammatory markers, helped us to identify the patients that needed immunosuppression (corticoids or selective cytokine blockade).

Increased inflammatory markers and lymphopenia were noticed in high percentages in our DM study group: severe cases were associated in 49 cases (100%) with positive increased biomarkers, moderate forms 35/40 (87.5%) and mild 6/19 (31%). Newly diagnosed DM and PD cases also had modified biomarkers, but with milder forms of SARS-CoV-2 pneumonia. Inflammatory markers were increased also in the second group emphasizing the severity of hospitalized cases.

Treatment included antidiabetic medication in group 1 (under multidisciplinary team adjustments). 44 patients (40%) required either the introduction of insulin or increased doses due to strong imbalances and daily monitoring of glycemic profile.

In all patients we indicated antiviral drugs upon severity and national guidelines (initially lopinavir / ritonavir, then remdesivir), corticoids (when hyperinflammation was obviously overexpressed and in severe cases), as well as hydroxychloroquine (first period of the pandemic) or tocilizumab, anticoagulants, oxygen therapy (in respiratory failure), antitussive, diarrhea drugs, IV rehydration and vitamins and a sustained psychological support.

We continued the specific medication for cardiovascular comorbidities (antihypertensive and lipid-lowering regimen (including ACE inhibitors and angiotensin 2 receptor-blockers) considered an indication by the European Society of Cardiology (ESC) in all these patients (15). After discharge, all patients were forwarded to ambulatory care units for a cautiously metabolic and cardiac monitoring and adjustment of specific treatment with oral antidiabetics or insulin, according to the evolution after COVID-19 recovery.

DISCUSSION

The high prevalence of DM and PD (33.4%) found in our group of patients with SARS-CoV-2 and the real difficulties for metabolic control achievement, represent addictional data that DM and hyperglycemia are major risk conditions for SARS-CoV-2 infection and for a severe evolution of the disease in hospitalized patients, needing special recommendations (8). Literature data offers several explanations for sustaining this particular group of patients with DM or PD.

Part of the renin-angiotensin-aldosterone system (RAAS), the ACE2 receptor is known to be the primary entry for SARS-COV2, expressed in many human cells and tissues, including the pancreatic islets (1, 16, 17). Studies showed an association between ACE2 and glucose regulation(18), moreover the infection with SARS-COV may be the cause of hyperglycemia in patients without pre-existing DM(19), by direct damage of the pancreatic -cells, which can persist several years after recovery from the infection(19). Two case series made in Seattle and Washington, USA, found that 58%, respectively 33% of the critically ill patients with COVID-19 that were admitted to the ICU had DM as an underlying comorbidity (20, 21). This evidence assumes that RAAS and the ACE2 receptor may have an implication in the connection between COVID-19 and DM.

At the same time the very high incidence of DM/PD met in our study is in concordance with the well-known data from the literature that infectious diseases are more prevalent among patients with DM than on those without(3, 8, 11). One important cause may implicate the hyperglycemic environment that favors immunological abnormalities, such as impaired cellular innate immunity function (low chemotaxis, phagocytosis) of monocytes/macrophages, low T-cells immune response and/or disturbances in humoral innate immunity (low complement factor 4, decreased cytokine response after stimulation) (3, 7), leading to micro- and macrovascular complications of DM (14, 22).

Pathophysiology of SARS-CoV-2 infection led to an elevated inflammatory response among blood mediators such as lipopolysaccharide (22, 23), inflammatory cytokines, toxic metabolites, modulation of natural killer cells with IFNy production (24), that in the end increase the vascular and/or interstitial permeability for pro-inflammatory products (25). Furthermore, the infection with SARS-CoV-2 leads to reactive oxygen species (ROS) production, causing acute lung damage with acute respiratory distress syndrome and lung fibrosis (25). Viral activation of RAAS via ACE2 and together with ROS production, cause insulin resistance (24), hyperglycemia and vascular endothelial damage (25), ending with cardiovascular events, disseminated intravascular coagulation (DIC) and thromboembolism (26).

Elevation of inflammatory markers such as ferritin, D-dimer, fibrinogen and IL-6 (27), contribute to a higher risk for patients with DM for hypercoagulability, sepsis progression and ICU admission (14, 28). Wang *et al.* in a retrospective multicenter study from China regarding fasting blood glucose at admission found out that higher levels (≥ 7.0 mmol/L (≥ 126 mg/dL) were independent predictors of COVID-19-related mortality for patients that did not have DM (29).

In our study, an important part of the group 37 patients 34.2% (17 with DM and 20 PD) presented *de novo* DM or persistent fasting hyperglycemia during SARS-CoV-2 pneumonia.

This observation highlights the importance of daily close monitoring glucose levels and to treat hyperglycemia on patients with progression to severe states of COVID-19. In our group of patients corticoid treatment could be, in addition to infection with SARS-CoV-2, another factor that unbalanced the DM and brought in the light the persistent hyperglycemia. But even after the use of very small doses of corticoids or after corticotherapy exclusion, glucose levels remained high, difficult to control. Thus, we reintroduced corticoster-

oids for their benefits (anti-edematous/anti-inflammatory effects - including the pancreas) and we increased the insulin doses (by subcutaneous or intravenous administration) and recommended a strict diet and adequate fluid intake. The permanent endocrinological consultation and the close monitoring of blood glucose (daily glucose profile - 5 samples) led slowly to improvement.

In a retrospective study performed in Sydney, Australia, eight critically ill patients with COVID-19 and T2DM, three being newly diagnosed, required extremely high doses of insulin (mean peak insulin requirement of 201 units per day) and had a delayed control of the glucose level at the time of peak inflammatory response (30), strongly supporting our study results.

We found that obesity is a major risk factor for the severe evolution of SARS-CoV-2 pneumonia both in DM and non-DM patients.

It is described that patients with COVID-19 and associated overweight or obesity, had worse outcomes than those without, because of the high-grade inflammation and of the compromised immune system (31, 32). Glucagon-like peptide 1 (GLP1) and its analogues are used in some patients with T2DM and cardiovascular comorbidities, with lowered rates of cardiac events (33) and may be a good therapeutic approach for patients with obesity, because of the weight-reducing properties (34), but not recommended in critical situations (e.g., severe cases of COVID-19) because of the slow target dose achievements and side effects such as nausea or vomiting (35).

Several retrospective cohort studies achieved in the USA, China and France analyzed the clinical outcomes regarding patients with COVID-19 and DM. The main features that have been measured were age (mean age), male/female ratio, glycemic status and glycosylated hemoglobin proportion (HbA1c), comorbidities, risk factors for mortality and primary outcomes. The number of patients included ranged from 153 in the China study to 1,317 in the French study. The mean age was 69.8±13.0 in France, 56.2–72.0 in China and 66.7±14.2 in the USA. Besides DM, most commonly discovered comorbidities found were hypertension, coronary heart disease, heart failure, chronic kidney disease and chronic obstructive lung disease. Primarily, added mortality risk factors were older age, male sex, micro and macrovascular complications, higher BMI and insulin administration before admission. In France, the death rate was 29% out of 1,317 patients in day 7 after admission, in China was 20% from a total of 153 patients, 11% being non-DM patients and 33% in the USA (1,276 patients) (36, 37, 38). The Center of Disease Control (CDC), based on a meta-analysis, declared that the risk of a fatal outcome from COVID-19 is 50% higher in patients with DM than in those who do not have DM (39).

In our study group a higher prevalence of DM/PD was noticed in the middle age (43.4% between 35–60-year-old) comparing with 35% found in the literature (12). The mean age in our first group was 62 years-old with a range between 37- and 85-year-old. We note a higher percentage in patients from the age group 61-80 and > 80-year-old in nondiabetic patients (71.66%). An explanation could be the fragility of diabetic patients against SARS-CoV-2 infection even in middle-aged people.

A huge percentage of patients associated obesity or overweight, 92% (bigger in women), 37% had coronary heart disease, 47.2% arterial hypertension, 17.6% COPD,

11.1% asthma and 8.3% renal disease. Cardiovascular comorbidities were in a mild lower frequency in the group 2, without DM. Obesity, COPD and asthma had comparable frequency in the two groups.

Severity of COVID was higher in the DM/PD group compared to the second group without DM: 17.6% *vs.* 53.4% mild forms, 37% *vs.* 27.9% moderate pneumonias, 45.3% *vs.* 18.6% severe forms. At the same time in group with DM/PD we found a surplus of severe forms compared to what has been found in the literature (20% severe forms) (13, 39).

In our DM/PD group of study the fatality (12%) was 4.8 times higher than the COVID-19-related mortality over the country (2.48%) (data from December 2020) (13). The fatality in the group without DM/PD (7.4%) was lower than in the DM/PD group but higher than the national value. Our observation reinforces the fact that DM is a severity factor for SARS-COV2 pneumonia. On the other hand, the high values of severe forms and high fatality in our groups could be explained by the fact that we studied the patients that were precisely hospitalized for severe evolution and our data did not include the general population infected with COVID-19.

After the COVID-19 recovery period, patients with DM or PD will have a strong indication for vaccination. There are not known medical contraindications for vaccination in patients that contracted COVID-19 and had underlying DM. According to CDC, patients with DM are included in the group 1c, as well as other medical conditions that can increase the risk of serious, life-threatening complications from COVID-19. Vaccination of DM patients will take place after 1a group - healthcare professional and long-term care facility residents and 1b group - people aged ≥ 75 years and frontline essential workers (39).

We recommended a close monitoring of patient in post COVID period (by clinical exam, thoracic ultrasound/thoracic scan upon severity, spirometry / bodyplethismography, pulsoxymetry and endocrinological consult) after discharge like a personalized management to prevent further unfavorable evolution and post COVID complications (pulmonary fibrosis, decompensation of the DM) (40).

CONCLUSIONS

DM and PD were important risk factors for an increased severity of SARS-CoV-2 infection and high fatality. SARS-CoV-2 infection determined DM imbalance and clinical *de novo* DM or highlighted PD. In the course of the COVID-19 pandemic, awareness should be raised among patients with underlying DM. Proper management and treatment enhancement (including insulin administration) are essential for a good control of glycemic levels. We found in our study group multiple comorbidities: obesity, overweight, hypertension, cardiac ischemic diseases and COPD and asthma that contributed to a severe evolution.

Obesity was a major risk factor for SARS-CoV-2 in both groups (with or without DM). The recommendation of close monitoring after discharge is part of a personalized management to prevent further unfavorable evolution and post COVID-19 complications. All patients with DM and PD have to follow a customized monitoring in the ambulatory care units for the entire post COVID-19 recovery period, for treatment adjustments.

STUDY LIMITATION. We appreciated the patients with SARS-CoV-2 association with DM/PD that were precisely hospitalized for severe evolution and our data

did not include the general population infected with COVID-19. Because of the high contagiosity of the SARS-CoV-2 infection, it was not possible during the hospitalization an exhaustive analysis of the DM complication.

DRY EYE SYNDROME IN PATIENTS WITH CARDIOVASCULAR PATHOLOGY (Abstract): The present study aims to open a new perspective in addressing patients suffering from the dry eye syndrome through the analysis of biometric markers that explain the long-term evolution of these patients, especially those with cardiovascular dysfunctions. **Material and methods:** In this study were included 200 patients from Comanesti County Hospital who were examined between 2016 and 2018. The cases were structured in 4 groups of 50 patients each, with or without cardiovascular disease, with or without dry eye syndrome. **Results:** Gender distribution showed a slightly higher proportion of women in all study groups. Dyslipidemia was identified in 70% of patients and hypertension in 66% of them. Other frequent pathologies identified in the study group were angina pectoris which was discovered in 28% of patients and diabetes mellitus which was found in 23.3% of them. Heart failure was found in 39% of all patients suffering from dry eye syndrome and it was significantly more frequent in women (57.5% *vs.* 26.7%). **Conclusions:** The heart failure was significantly more common in women and in those aged over 60 years for whom the estimated risk was more than 2.5 times higher in the whole group and about 2 times higher in patients suffering from the dry eye syndrome. Central corneal thickness, corneal resistance, corneal hysteresis are good predictors of the dry eye syndrome with/without cardiovascular damage. **Keywords:** DRY EYE DISEASE, CORNEAL THICKNESS, CARDIOVASCULAR DISEASE, HYPERTENSION.

The purpose of study was to elucidate the correlation of pathophysiological mechanisms and predisposing factors involved in the occurrence of the dry eye syndrome and/or cardiovascular diseases of symptomatic patients, all this for a better life`s quality of patients.

The dry eye syndrome occurs in adults, more commonly after the age of 50-60 years, with females predominating in 90% of cases. The tear secretion is characterized by a significant decrease in aqueous secretion which is also associated with the alteration of the mucin layer of the tear film; the mucin, easily coming into contact with the lipids of the superficial layer, precipitates and stagnates due to the reduction of the aqueous phase. Due to the decrease in aqueous flow on the one hand and the antibacterial lysozyme and lactoferrin on the other, the possibility of developing local infections is high (1-4).

The term *"cardiovascular disease"* (CVD) is attributed to a multitude of dis-

eases affecting the heart and blood vessels, including ischemic heart disease (IHD), cerebrovascular disease, hypertension (high blood pressure) or peripheral arterial disease (PAD). Other cardiovascular diseases are myocarditis (a heart condition caused by rheumatic fever) and congenital heart diseases. The cardiovascular diseases are also associated with heart attacks (myocardial infarction), angina and strokes (5).

MATERIAL AND METHODS

Study lots

The study group consisted of 200 patients selected from Comanesti County Hospital between 2016 and 2018. The study group was divided into four lots according to the presence/absence of the dry eye syndrome and / or cardiovascular comorbidities:

Lot I - 50 patients suffering from the dry eye syndrome with various associated cardiovascular comorbidities;

Lot II - 50 patients suffering from the dry eye syndrome but without associated cardiovascular comorbidities;

Lot III - 50 patients suffering from a cardiovascular disease without suffering from the dry eye syndrome;

Lot IV - 50 apparently healthy patients, chosen as witness group, not suffering from the dry eye syndrome or cardiovascular diseases.

The inclusion criteria were:

- age over 18;
- preoperative diagnosis of the dry eye syndrome;
- significant cardiovascular pathology (grade 3-4 hypertension with high/very high additional risk, NYHA class III heart failure, etc.);
- biochemical parameters within normal limits, allowing ophthalmic surgery.

Exclusion criteria:

- association of neoplasms;
- the refusal to participate in the study or the presence of a psychiatric disorder that does not allow informed consent to be understood;
- other pathologies of the eye (acute/chronic infections) that may affect the biochemistry of the tear film.

The study followed cardiovascular risk factors that cannot be influenced: gender, age, family history (genetic predisposition) and cardiovascular risk factors that can be influenced: obesity, high cholesterol, stress, hypertension, smoking, diabetes, sedentary lifestyle.

The study was approved by the Ethics Committee of "Grigore T. Popa" University of Medicine and Pharmacy from Iasi and is part of a Ph.D. study. Informed consent was obtained from each patient.

Statistical analysis was carried out using *SPSS 20.0* software. For all data, p value <0.05 was considered statistically significant.

RESULTS

The gender distribution showed a slightly higher proportion of women in all study groups, especially in patients from group I (suffering from the dry eye syndrome and a cardiovascular disease) ($p=0.160$) (fig. 1).

The age of the patients ranged from 29 to 85 years, with a group mean age of 61.05 ± 10.30 years and was slightly higher in patients suffering from the dry eye syndrome and a cardiovascular disease (group I: 64.76 years; $p=0.118$). Data are presented in first table.

The weight status did not differ significantly between the study groups. However, it should be noted that the mean BMI level

was slightly higher in patients suffering from cardiovascular diseases without the dry eye syndrome (31.24 kg/m^2; p=0.662) (fig. 2).

Lot III	50	60.76	11.63	2.82	54.78	66.75	29	76	0.118
Lot IV	50	58.08	9.94	1.44	55.20	60.97	40	82	
TOTAL	200	61.05	10.30	0.82	59.42	62.68	29	85	

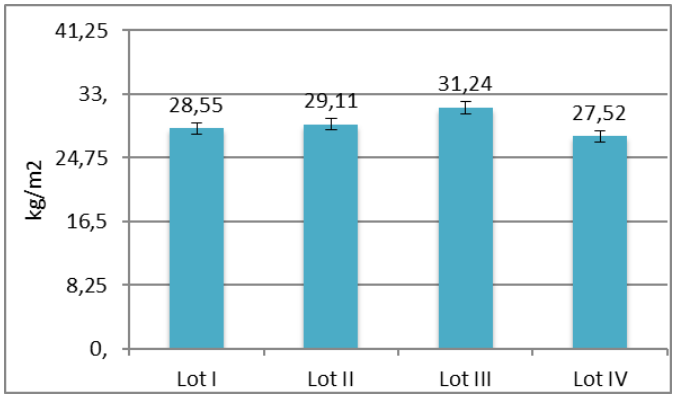

Fig. 2. The comparative weight status by study groups

The heart failure was present in personal pathological history in 34.5% of patients, significantly more frequently in women (60.9% *vs.* 20.6%). The relative risk was about 3 times higher (p=0.001; RR=2.96; 95% CI:1.84-4.75) for these patients. According to NYHA classification on the studied case reports, stage III heart failure was observed in 9.9% of men and stage IV in only 2.3% of them, while in women predominated stage II (29%) and III (23.2%). Heart failure was significantly more common in those aged over 60 years (45.9% *vs.* 20.9%). The relative risk was 2.57 times higher in these cases (p=0.022; RR=2.57; 95% CI: 1.39-4.75). Stages II (19.3%) and III (22%) of heart failure are more common in geriatric age groups according to NYHA staging (tab. II, fig. 3).

Heart failure was found in 39% of all patients suffering from dry eye syndrome and it was significantly more frequent in women (57.5% *vs.* 26.7%). The relative risk was about 2 times higher in this situation (p=0.049; RR=1.95; 95% CI: 1.33-4.15) but with equal weighting by age group (29%) (tab. II, fig. 3).

The angina pectoris was stable in 28% of patients, having no significant percentage differences between gender: 29.9% men and 19% women (p=0.446; RR=1.57; 95% CI: 0.63-3.95) or age groups: 31.5% in patients under 60 years and 25.3% in those over 60 years (p=0.515; RR=1.24; 95% CI: 0.74-2.08).

Hypertension was present in 66% of patients, with no significant percentage differences between gender: 71.4% of women and 64.8% of men (p=0.751; RR=1.10; 95% CI: 0.81-1.48) or age groups (p=0.686; RR=1.07; 95% CI: 0.85-1.35).

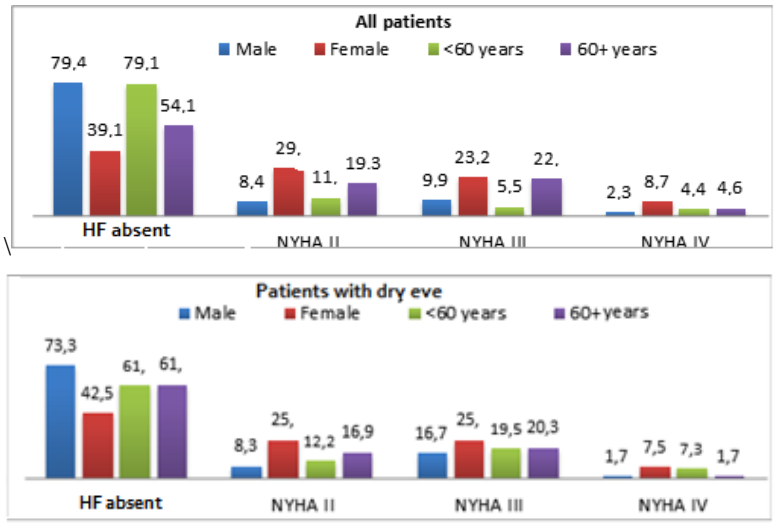

Fig. 3. The distribution of heart failure cases by gender and age group

Diabetes mellitus was identified in 23.3% of patients. The gender distribution was 33.3% in women and 21.7% in men, inducing a slightly higher relative risk in females (p=0.373; RR=1.54; 95% CI: 0.77-3.06). Diabetes was identified in 27% of patients under 60 and 19.7% of those over 60, but the percentage differences were not statistically significant (p=0.388; RR=1.37; 95% CI: 0.76-2.47).

Dyslipidemia was present preoperatively in 70% of patients and the gender distribution was 76.2% in women and 69% in men, with statistically insignificant percentage differences between genders (p=0.681; RR=1.10; 95% CI: 0.85-1.44). The percentage distribution of cases with dyslipidemia according to the age group was 81.1% in patients under 60 years of age compared to 59.2% of those over 60 years of age, with a slightly higher relative risk at younger ages (p=0.006; RR=1.37; 95% CI: 1.10-1.70).

Biometric evaluation

Central corneal thickness (CCG) ranged from 481 to 634 µm, with no significant differences in average levels compared by study groups (tab. III).

The lowest average intraocular pressure (IOP) level was recorded in patients suffering from the dry eye syndrome with various cardiovascular comorbidities (group I) and the highest was recorded in patients suffering from the dry eye syndrome without cardiovascular comorbidities (group II) (16.13±2.94 mmHg *vs.* 18.31±4.19 mmHg; p=0.004) (tab. III).

Individual corneal hysteresis (HC) values exceeded 10.8±1.5 mmHg in 7.7% of patients. The lowest average level was found in patients suffering from dry eye syndrome without any cardiovascular comorbidities associated (group II) (9.39±1.56 mmHg; p=0.001) (tab. III).

The corneal resistance factor (CRF) ranged from 8 to 18 mmHg and recorded a significantly lower average level in the groups suffering from the dry eye syndrome compared to the highest average level recorded in the group with cardiovascular diseases only (group I and II *vs.* group III) (10.97±1.68 mmHg; 10.45±2.09 mmHg *vs.* 12.15±2.53 mmHg; p=0.011) (tab. III).

TABLE IV

Multivariate analysis. Dependent variable of the dry eye syndrome.

Model	R	R square	Adjusted R square	Err. Std. of estimation	P F Change
1. Age	0.236	0.056	0.050	1.176	0.003
2. Age. CCG	0.237	0.056	0.044	1.180	0.760
3. Age. CCG. FRC	0.275	0.076	0.057	1.171	0.077
4. Age. CCG. FRC. HC	0.342	0.117	0.093	1.149	0.009
5. Age. CCG. FRC. HC. PIO	0.409	0.167	0.128	1.127	0.006

The multivariate linear analysis confirms the following:

- The linear regression model 4 (p=0.009) highlights as good predictors in the determinism of the dry eye syndrome and/or cardiovascular damage: age, central corneal thickness, corneal resistance and corneal hysteresis;
- The linear regression model number 5 (p=0.006) highlights, in addition to

age, central corneal thickness, corneal resistance and corneal hysteresis as good predictors in the determinism of the dry eye syndrome and/or cardiovascular damage and intraocular pressure.

DISCUSSION

Dry eye disease is more frequent in women than men and has an increased prevalence with age (3). The prevalence of dry eye syndrome varies from approximately 5 to 50% in population-based studies. Approximately 1 out of 7 individuals with ages between 65 to 84 years old reports frequently symptoms of dry eye (4).

Most cardiovascular diseases can be prevented by measures that address behavioral risk factors: smoking, unhealthy diet, sedentary lifestyles, obesity, alcohol in unhealthy doses. A low standard of living, a disadvantaged social background and educational deficiencies dramatically reduce the adherence to these prophylactic measures. The ageing of the population should also be mentioned, as age is a non-influential risk factor for cardiovascular disease (5).

Recent studies of dry eye disease classification and epidemiology suggest that a patient with dry eye may have multiple etiologies (6-9). In our study, dyslipidemia was identified in 70% of patients and hypertension in 66% of them. Other frequent pathologies identified in the study group were angina pectoris which was discovered in 28% of patients and diabetes mellitus which was found in 23.3% of them. These results are similar with a study conducted in 2018 that identified hypertension, thyroid disease, type 2 diabetes, sleep apnea, depression, and cardiovascular diseases associated with dry eye syndrome (6).

Type 2 diabetes represents a common risk factor for ocular diseases (10). A study conducted by Chew *et al.* showed that diabetes was found in more than 24% of those with newly diagnosed and prevalent dry eye disease (11). These results are similar with the ones found in our study.

In our study, across all comorbidities evaluated, hypertension was the most commonly observed cardiovascular comorbidity and was found in 66% with or without dry eye disease. These findings are similar with the ones from a study conducted by Dana *et al.*, who found that hypertension was the most frequent comorbidity in both groups with or without dry eye disease (6).

A study conducted by Butovich *et al.* showed that the relationship between hypercholesterolemia and dry eye disease can be explained as the high levels of cholesterol in the meibomian lipid will lead to increased viscosity and plugging of the meibomiam orifice (12). In our study. dyslipidemia was identified in 70% of patients.

Numerous epidemiological studies noted that dry eye prevalence increases in women and men every five years after the age of 50, with higher prevalence in women compared to men (13-19). Age and female sex have been found to represent the most important risk factors for dry eye. These findings are supported by the reduced tear production in women through the sixth decade of life (20-22). These results are similar with the ones found in our study where the gender distribution showed a slightly higher proportion of women in all study groups, with a mean age of 61.05 years old.

In our study of all patients suffering from the dry eye syndrome, 39% of them had a history of heart failure, significantly

more frequently in women (57.5% *vs.* 26.7%), for whom the relative risk was about 2 times higher. These results are similar with the ones found in a study conducted by Shokr *et al*. in 2021, which showed that patients with positive diagnosis of dry eye disease present a higher risk for developing cardiovascular diseases (23).

A study conducted by Borrego-Sanz *et al.* showed that dry eye disease associated with Sjögren's syndrome can influence corneal biomechanical properties (24). In our study. central corneal thickness, corneal resistance and corneal hysteresis turned out to be important predictor factors for dry eye disease.

CONCLUSIONS

There were no significant percentage differences in sex. age and weight status characteristics in relation to the association of the dry eye syndrome with/without cardiovascular impairment.

Heart failure was significantly more common in women (60.9%) over the age of 60 (45.9%), with an estimated risk more than 2.5 times higher in the whole group and about 2 times higher in patients suffering from the dry eye syndrome.

Central corneal thickness, corneal resistance and corneal hysteresis are good predictors of the dry eye syndrome with/without cardiovascular damage.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding the scientific research.

NEWS

BELATACEPT - A GOOD OPTION AS AN IMMUNOSUPPRESSIVE DRUG IN LIVER TRANSPLANT

Judicious use of immunosuppression is imperative after liver transplantation to achieve an adequate level of immunosuppression while also balancing dose-dependent adverse effects associated with these medications. Authors describe the successful use of belatacept-based immunosuppression in a liver transplant recipient who experienced treatment related adverse effects to first- and second-line immunosuppressive agents. Six months post-initiation belatacept-based immunosuppression, the patient had stabilization of his chronic kidney disease, improvement in lung function, and remains without evidence of rejection. Belatacept is a novel, first in class, fusion protein that blocks signal 2 of T cell activation. However, before routine use of belatacept in liver transplant recipients can be recommended, further safety and efficacy data are needed. (Lang K, Kane C, Van Wagner BL. Belatacept as salvage maintenance immunosuppression in a liver transplant recipient. *Transplantation Reports* 2020; 5: 100070).

CHRONIC OBSTRUCTIVE PULMONARY DISEASE - OBSTRUCTIVE SLEEP APNEA OVERLAP SYNDROME CHOOSING THE RIGHT POSITIVE PRESSURE THERAPY

CHRONIC OBSTRUCTIVE PULMONARY DISEASE - OBSTRUCTIVE SLEEP APNEA OVERLAP SYNDROME CHOOSING THE RIGHT POSITIVE PRESSURE THERAPY **(**Abstract): Patients with chronic obstructive pulmonary disease (COPD) - obstructive sleep apnea (OSA) overlap syndrome have worse outcomes than patients with either COPD or OSA alone. Positive pressure therapy (continuous positive airway pressure - CPAP or non-invasive ventilation - NIV) is still a matter of debate. The **aim** of the study is to identify clinical (symptoms, changes in physical examination) and paraclinical (spirometry, arterial blood gases and respiratory events during sleep) parameters that could orientate the physician towards choosing a certain type of positive pressure therapy in patients with COPD-OSA overlap syndrome. **Material and method**: 84 patients with overlap syndrome were included. A very thorough anamnesis, physical examination, blood samples, spirometry and ventilatory polygraphy was performed in all patients. **Results:** Most patients had severe sleep apnea with an average of 38 events per hour of sleep, and moderate COPD - stage II GOLD. The positive therapy used was mainly CPAP (57%), and the preferred mask was oronasal. **Conclusions:** Patients with overlap syndrome appear to prefer CPAP as positive therapy treatment and oronasal mask as interface. However, we could not establish any correlation between any clinical, functional or ventilatory polygraphy parameters that could explain the choice of one or another type of positive pressure devices. **Keywords:** COPD, OSA, OVERLAP SYNDROME, OBSTRUCTIVE SYNDROME, DAYTIME SLEEPINESS.

Obstructive sleep apnea (OSA) is a common comorbidity in patients with chronic obstructive pulmonary disease (COPD) (1). The term "overlap syndrome" refers to the association of the two conditions in the same patient - COPD-OSA

overlap syndrome (OVS). These patients have in general a worse prognosis compared with those with either OSA, either COPD due to the significant desaturation during the night with longer periods of hypoxemia and/or hypercapnia.

The triad that clinically characterizes obstructive sleep apnea is snoring, sleep apnea, and excessive daytime sleepiness in a typically male patient, obese, active, or former smoker (2, 3, 4, 5). Cardiovascular complications are present in both those with OSA and COPD (6, 7, 8). In patients with OVS, however, arterial hypertension, arrhythmias, pulmonary hypertension, ischemic heart disease occur more often and earlier in the course of the disease. Positive pressure therapy, at least in patients with OSA, appears to reduce the costs associated with healthcare and mortality. The choice of continuous positive pressure (CPAP) versus non-invasive ventilation (BiPAP) in patients with OVS is still the subject of much debate (7, 8, 9, 10, 11, 12). While some authors suggest that CPAP is as effective as bilevel positive airway pressure (BiPAP) in patients with OVS (7-9) there are some who recommend adjusting the therapy according to the severity of the lung involvement, practically the severity of COPD (10, 11, 13). The main reason for prescribing long term non-invasive ventilation in patients with OSA and/or COPD is persistent hypercapnia ($PaCO_2$ > 45 mmHg). The main question is however: what causes CO_2 elevation in patients with OVS? Is it only the COPD or has obstructive sleep apnea a certain contribution, and the use of CPAP improves ventilation by reducing $PaCO_2$ such as in patients with hypoventilation obesity syndrome? (12, 13). The question is even more interesting as obstructive sleep apnea seems to be more common among patients with mild to moderate COPD (FEV1 > 50%). The more severe the COPD, the lower the likelihood of developing OSA. In other words, the patients that are more prone to develop hypercapnia are most unlikely to have obstructive sleep apnea. CPAP, in addition to improving survival in patients with OVS, is also effective in reducing COPD exacerbations (14-19).

Therefore, **the aim of the present study** is to identify clinical (symptoms, changes in physical examination) and paraclinical (spirometry, arterial blood gases, respiratory events during sleep) parameters that could orientate the physician towards choosing a certain type of positive pressure therapy in patients with COPD-OSA overlap syndrome.

MATERIAL AND METHODS

It is a prospective, observational study performed in the "Leon Daniello" Clinical Hospital of Pneumology in Cluj Napoca between 2019 and 2020.

Study population: were included 84 patients hospitalized for sleep study and with newly diagnosed COPD (diagnosed made according to GOLD guideline 2019) (1). Initial evaluation included a very thorough anamnesis and physical examination performed by the same physician. All patients completed the Epworth Sleepiness Scale (ESS). Blood samples, arterial blood gases, spirometry and cardio-respiratory polygraphy was performed in all patients. The polygraphy was performed using the Nox Medical polygraph, Model 8000. The data were interpreted using the NOXTURNAL software version 4.4.2.14926/2016. All results were manually validated by the same doctor with competence in sleep medicine. The validation and interpretation

were performed according to the recommendations of the American Sleep Society 2007. If the apnea-hypopnea index (AHI) was > 15 events / hour of sleep, patients were offered CPAP. To ensure a better titration quality, the patient slept one night only with the positive pressure device without the polygraph. Titration was performed depending on the result of the polygraphy and the presence or absence of hypercapnia with CPAP (DV 54 Auto adjust CPAP, ResMed) or BiPAP S or S / T (DV 57AutoBilevel, ResMed). The initial pressures for auto CPAP were the positive end-of-expiratory pressure (EPAP) minimum of 4 cmH_2O, and maximum depending on the patient's tolerance up to 20 cmH_2O. If the pressures needed by the patient were too high or not tolerated by the patient, or if hypercapnia was present then CPAP was replaced with BiPAP. For BiPAP: EPAP was at least 6 cmH_2O and IPAP varied, being at least 10 cmH_2O. Masks used were FlexiFit407 and F&P Simplus (Fisher and Paykel), nasal or oronasal mask depending on the patient's preference or patient characteristics (mouth breathing, nasal obstruction).

Statistical analysis

Data was analyzed using *IBM SPSS STATISTICS 25.0 for Windows*. The normal distribution of continuous variables was tested using the Kolmogorov-Smirnov test. The median [25th percentile (Q1) and 75th percentile (Q3)] was calculated for the quantitative variables with normal distribution. In the case of non-normally distributed quantitative variables, they were expressed using mean ± standard deviation. Qualitative variables were expressed in numbers / frequencies and percentages. To evaluate the association between two quantitative variables, the Pearson correlation coefficient was calculated if the variables were linear and the Spearmen's coefficient, otherwise.

RESULTS

84 patients with COPD - OSA overlap syndrome were included in the study. The clinical characteristics and paraclinical parameters (arterial blood gases, spirometry, cardio-respiratory polygraphy values) are summarized in table I A and I B.

TABLE I A

Patients demographic characteristics

Parameter	Frequency
Gender	
Male	71 (82.6%)
Female	15 (17.4%)
Environment	
City	55 (64%)
Countryside	29 (33.7%)
Smoking status

TABLE IB
Patients clinical characteristics

Parameters	Median 25th percentile; 75th percentile (mean ± SD)
Age (years old)	61 (51; 66)
Height (m)	1.7 (1.66; 1.75)
Weight (kg)	110 (100; 122)
BMI (kg/m²)	37.37 (33.25; 41.8)
EPWORTH score	9.5 (6; 16)
Pack-a-year index	21.25 (0; 35.5)
Neck diameter	46.04 ± 3.73
Abdominal circumference	128.66 ± 14.33
Abdominal-waist index	1.08 ± 0.09
AHI	38.2 (22.4; 63.9)
ODI	43.85 (22.4; 72.4)
Min O_2 saturation	73.5 (61; 81)
Average O_2 saturation	89 (85; 92)
HR average	67 (61; 75)
HR max	103.5 (89; 116)
HR min	48 (37; 53)
FVC (L) **FVC (%)**	2.69 ± 0.86 72.75 ± 21.44
FEV1 (L) **FEV (%)**	2.03 ± 0.84 67.05 ± 24.81
FEV1 / FVC	66.2 (63.54; 68.98)
MEF 50 (L) **MEF 50 (%)**	1.74 (0.9; 2.8) 45 (26.95; 71.8)
HCO_3	27.3 (25.5; 29.8)

The patients were symptomatic with an Epworth score of 9.5 (6; 16) out of 24. After obesity, the most common comorbidity was arterial hypertension. As for COPD treatment most, patients had a combination of inhaled corticosteroids and a bronchodilator (either long acting muscarinic or beta2 agonist) (tab. IA). In the studied population, sleep apnea syndrome was severed with the predominance of apnea (21.91 ± 17.34 events per hour of sleep, while hypopnea were 19.1 (9.6; 29.3) Desaturation index was 43.83/hour of sleep with significant desaturation during the night (tab. IB). COPD was moderate (FEV1 = 67.05 ± 24.8% of predicted) and arterial blood gases were characterized by mild hypoxemia 69.36 ± 11.39 mmHg and mild hypercapnia 42.5 mmHg (39; 46.3). The lower the oxygen saturation measured by ABG was, the

lower the FVC measured in liters (L) and percentage. Regarding the symptoms reported by patients with OVS, the predominance of snoring is observed from afar, which is found in 90.7% of patients, followed by daytime sleepiness (74.4%) - Epworth score of 9.5 and morning headache (72.1%). Nocturnal dyspnea (70% of patients), nycturia (61% of patients) and insomnia (67%) were also very frequent among patients with OVS. Positive pressure therapy of patients included in the study was mainly CPAP (57%), with a mean pressure of 8 cmH_2O (tab. II). Patients who needed non-invasive ventilation (BiPAP) were ventilated in Bi-PAP S mode with a mean IPAP of 18 cmH_2O and a mean EPAP of 8 cmH_2O. The most used interface was the oronasal mask. EPAP was higher the more severe the obstructive sleep apnea.

TABLE II

Treatment with positive pressure of patients with overlap syndrome

Parameter	Frequency	Mean ± SD
Device **BiPAP** **CPAP**	 36 (43%) 48 (57%)	
IPAP (cm H_2O)		18 (16; 20)
EPAP (cm H_2O)		8 (6; 10)
Interface **Nasal mask** **Oronasal mask**	 28 (30.2%) 56 (62.8%)	
Associated oxygen therapy	26 (30.2%)	

DISCUSSION

84 patients with COPD-OSA overlap syndrome who presented to the pulmonology department for sleep studies were evaluated. Most patients had severe sleep apnea with an average of 38 events per hour of sleep, and moderate COPD - stage II GOLD (FEV1 = 67.2% of predicted value). The positive therapy used was mainly CPAP (57%), and the preferred mask was oronasal. Our results are like those reported in the literature: CPAP appears to be the most used therapy in the treatment of patients with OVS (2, 3, 14-17). The data are however scarce, and the official recommendations sometimes contradictory. It is still debatable if CPAP or BIPAP should be prescribed for OSV. Which patients? In which conditions? One of the main reasons for prescribing non-invasive ventilation in OVS patients is persistent hypercapnia $PaCO_2 > 45$ mmHg, due mainly to type II respiratory failure a common complication of COPD patients. There are patients with OSA that could present with hypercapnia that does not correct with CPAP. Therefore, even though McNichols (8) proposed as therapeutic algorithm the use of CPAP if OSA has the predominant features and BiPAP if the COPD it's the predominant diseases, we still don't know in what measure the presence of OSA contributes to the presence of hypercapnia.

Secondly there are few particularities

that may explain patient's preference for CPAP in the present study: 1) **The population** - the present study was performed on patients who presented for sleep apnea on their own initiative and the diagnosis of COPD was made afterwards, in the clinic. This situation is quite different from patients with known COPD that would come for evaluation or with exacerbation and it would be proposed to perform ventilatory polygraphy to diagnose obstructive sleep apnea. From the beginning we have patients in whom the clinical picture is dominated by sleep apnea, so, according to the existing data we will be more prone to prescribe CPAP. Since they came on their own initiative we can suspect a greater interest in their own health, unlike COPD patients who come with exacerbation, an indirect sign of the fact that they neglect the treatment, therefor their disease. Moreover, we observed in our patients a high Epworth score (9.5 out of 24) which means that the patients were very symptomatic, and sleepiness affects greatly life quality. As reported in several studies the symptomatic patients are more likely to follow the treatment that those without symptoms (8, 9, 10, 11). We must consider, nevertheless the low sensibility of Epworth in evaluating daytime sleepiness. It has a sensibility (Se) of 27-72% and a specificity of 50-76% and a diagnostic accuracy of up to 59% for mild form obstructive sleep apnea (AHI = 5-15/ hour of sleep) and a Se = 36%, Sp = 77% for moderate and severe SASO (AHI > 15 / hour of sleep) (4). An ideal situation would be to have a comparative group of patients with OVS where COPD is the predominant disease. According to existing data, patients with obstructive sleep apnea prefer the nasal mask. It has less contact with the face compared to the oronasal face and brings an additional benefit to the patient by minimizing side effects, especially pressure lesions. There are also fewer losses (7, 8, 11, 13, 14). However, they are more difficult to tolerate, especially when the ventilation pressures are high. This may be one of the reasons why our patients preferred the oronasal mask. Educational, supportive, and behavioral interventions are very important, helping patients to accept the need for regular use of therapy (13).

2) **The patients must pay for their therapy**. In our country positive pressure therapy is not reimbursed by the National Insurance House in sleep apnea or COPD patients. Given the purchase costs, which are often prohibitive for patients, most people resort to renting the device. The cost of rent, depending on the distribution company and the characteristic of the device varies between 180-250 Ron (Romanian money) - for a CPAP, and for a BIPAP depending on the characteristics and ventilation modes offered varies between 250-350 (S, S / T), 600 - 1000 those with hybrid modes (AVAPS, AVAPS-AE, iVAPS). There should also be considered mask cost, which should normally be replaced annually. The high costs of therapy are one of the main reasons why patients either refuse the device or are not compliant to the therapy. There are companies that, under certain conditions, offer free mask (usually nasal). Despite that, however patients still prefer oro-nasal mask (25, 26). We must take this in consideration when analysis the present study results, and we consider it to be one of studies strengths despite its limitations: 1. it's performed in a single center, on a small sample; 2. the OSA diagnosis was done using ventilatory polygraphy and not nocturnal polysomnography and some patients might have been missed. Oxygen saturation, assessed by ABG, was positively correlated with age and FVC measured

in liters and percentages predicted ($r = 0.324$, $p < 0.012$). The interest of this observation lies in the fact that in older patients with OVS only positive pressure therapy may not be sufficient, additional oxygen may also be needed.

CONCLUSIONS

The positive pressure therapy used in patients with OVS seems to be CPAP and the preferred mask the oronasal mask. However, it is not possible to establish a correlation between any clinical, functional or ventilatory polygraphy parameter that could explain the choice of one or another of the devices.

Particular reason for CPAP preferences in the present study might be the studied population (patients that come for sleep studies) and the non-reimbursed therapy cost in our country.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding the scientific research.

NEWS

BISULFITE PYROSEQUENCING AS A FIRST LINE DIAGNOSTIC TOOL OR SILVER-RUSSELL SYNDROME

Silver-Russell syndrome (SRS) is a pre- or post-natal growth retardation disorder caused by (epi)genetic alterations. The molecular basis and clinical value of sequential epigenetic analysis in pediatric patients with SRS were evaluated. 28 patients who met ≥ 3 Netchine-Harbison clinical scoring system (NH-CSS) criteria for SRS were enrolled. Methylation-specific multiplex ligation-dependent probe amplification (MS-MLPA) was performed as the first diagnostic step and then bisulfite pyrosequencing (BP). BP for 11p15 detected methylation defects in the 11 patients for whom a diagnosis was obtained using MS-MLPA and in three patients (10.7%) who did not show abnormal results on MS-MLPA. In contrast to MS-MLPA, BP analysis provides quantitative values for methylation abnormalities and increases the diagnostic yield, particularly in cases with mild and marginal methylation abnormalities. Therefore, BP should be considered in patients for whom a diagnosis of SRS is highly suspected, even if they showed negative results in MS-MLPA. (Soo YK, *et al*. Clinical Application of Sequential Epigenetic Analysis for Diagnosis of Silver-Russell Syndrome. *Ann Lab Med* 2021; 41(4): 401-408).

ADIPOKINE PROFILE AND METABOLIC SYNDROME IN PATIENTS WITH SIMILAR ADIPOSE TISSUE MASS AND DISTRIBUTION

ADIPOKINE PROFILE AND METABOLIC SYNDROME IN PATIENTS WITH SIMILAR ADIPOSE TISSUE MASS AND DISTRIBUTION (Abstract): In order to establish more efficient ways to prevent metabolic syndrome (MetS) in clinical settings, we need to thoroughly understand the physiopathology behind this cluster of risk factors for cardiometabolic diseases. The main point of focus concerning MetS still embraces the metabolic and secretory products of the abdominal adipose tissue. Our study aims to clearly define an adipokine profile for patients with MetS and assess possible correlations between obesity parameters, biochemical markers and adipokines. **Material and methods**: This is a cross-sectional study, elaborated over a period of two years, which involved 104 patients divided into 2 groups: with MetS and without MetS. Patients were considered as having MetS if they presented WC > 88 cm (women) / 104 cm (men) and more than one criterion of the following: glucose ≥ 100 mg/dL, HDL < 40 mg/dL (men) / < 50 mg/dL (women), TG ≥ 150 mg/dL, SBP/DBP ≥ 130/85 mmHg. Dual-Energy X-ray Absorptiometry (DEXA) was performed to assess adipose tissue distribution. All patients underwent clinical and paraclinical evaluation, including the measurements of insulin, adiponectin and leptin. **Results**: Leptin levels present a strong and positive correlation with almost all obesity parameters evaluated, with or without MetS. The strongest correlation is observed for trunk fat percentage (without MetS: r=0.648, p<0.001; with MetS: r=0. 723, p<0.001). In the group of patients without MetS adiponectin level is not associated with fat percentages, whereas in the group of patients with MetS adiponectin reports a weak and positive correlation between total fat, arms fat and legs fat percentages. Adiponectin is negatively correlated with HOMA-IR and insulin in both groups, suggesting that insulin resistance is linked to the change in adiponectin levels. Patients that present MetS also report an association between HDL and adiponectin (r=0.280, p=0.02). **Conclusions**: Patients with MetS that did not follow prior treatment for any chronic disease and are characterized by similar adipose tissue percentage and distribution, report the following: lower adiponectin levels than patients without MetS, but still a positive association with HDL; no modification in leptin levels compared to patients without MetS; negative correlation between adiponectin and insulin resistance; strong association between leptin and adipose tissue mass. **Keywords:** ADIPOKINES, ADIPOSE TISSUE, OBESITY, METABOLIC SYNDROME.

Adipose tissue is an active and complex endocrine organ, with important implications in glucose and lipid metabolism. The development of metabolic syndrome (MetS) focuses mainly on high abdominal fat, considered the most pathogenic depot that contributes to metabolic abnormalities (1, 2). The pathways that describe MetS are not yet clearly explained in the literature and debates still arise when the role, consequences and regulation of the secretory function of the adipose tissue is being discussed.

Adipokines are a class of cytokine mediators secreted by adipose cells. Adiponectin and leptin are two of the most studied adipokines, presenting opposite effects (3). Adiponectin has anti-atherogenic, anti-inflammatory and anti-diabetic properties (4, 5), while leptin promotes inflammation immune response and high cardiovascular risk (6). Thus far, the specific values of these adipokines vary among study populations with MetS. A possible bias might be the medication participants are taking for chronic diseases in studies or maybe the adiponectin or leptin paradox already present.

Therefore, a correct interpretation of the values for adiponectin, leptin and their ratio are very important in order to thoroughly stratify the pathologies the patient is at risk for (dyslipidemia, diabetes mellitus, hypertension). The first step of our study was to assess an adipokine profile in patients with MetS, but with no prior treatment, no known chronic disease and no antecedent acute atherosclerotic pathology. The next step was to identify and compare possible correlations between fat mass, MetS biochemical parameters and adipokine levels, alongside insulin and insulin-resistance, in patients with or without MetS.

MATERIAL AND METHODS

Our study was conducted over a period of 2 years and included participants that did not present any known chronic disease and had no antecedent acute atherosclerotic pathology. The study was approved by the University Ethics Committee, number 1/27.07.2020 and all participants signed an informed consent before entering the study. Exclusion criteria included pregnant women and patients that refused to sign the informed consent. All investigations were performed by trained personnel, in the same clinic and laboratory, using the same tools and analyzers, during the entire study.

The population included in the study was divided into two groups: one group of patients that presented MetS (35 participants) and one group without MetS (69 participants). The status of MetS was defined as present if patients had waist circumference (WC) > 88 cm (women) / 104 cm (men) and met at least 2 of the following criteria: glucose ≥ 100 mg/dL, HDL < 40 mg/dL (men) / < 50 mg/dL (women), TG ≥ 150 mg/dL, SBP/DBP ≥ 130/85 mmHg (7).

Clinical and
anthropometric measurements

Prior to clinical evaluation, patients did not engage in physical exercise at least 30 minutes before and did not consume caffeine or alcohol. Anthropometric parameters were measured: height (tape meter stadiometer), weight (Tanita BC730), waist and hip circumference (flexible tape) at the umbilical and greater trochanter level, respectively. Blood pressure was measured twice with a valid automated device and a mean value was considered.

Adiposity measurements

In order to accurately appreciate adiposity percentages and fat mass values, along-

side lean mass and bone mineral content, Dual-Energy X-ray Absorptiometry (DEXA) was used, as a gold standard for this measurement. We report values expressed as kg of adipose tissue per whole body/specific areas of the body or percentages of adipose tissue calculated from total body weight or a specific area weight (left and right arm, left and right leg, trunk).

Biochemical parameters

Patients included in the study were evaluated during morning time, blood samples being collected after 12 hours overnight fast. Serum samples were obtained after centrifugation at 4°C and 4,500 x g, for 10 minutes. To avoid preanalytical errors, samples were transported to the laboratory within a 2-hr. frame, with a special isothermal bag for biological samples. There was an exception for insulin, which required sample centrifugation in maximum 15 minutes after collection. Serum for insulin, adiponectin and leptin was stored in separate tubes at -20°C.

Insulin levels were measured using an enzyme-labeled chemiluminescent immunometric assay kit, Immulite 2000 Insulin, provided by Siemens (catalog number L2KIN2). Quantitative determination of the adiponectin and leptin levels was performed using enzyme-linked immunosorbent assay (ELISA) kits supplied by Biovendor-Laboratorni medicina a.s., Brno, Czech Republic: Adiponectin Human ELISA Competitive kit, CE-IVD, limit of detection 26 ng/mL, catalog number RD195023100 and Leptin Human ELISA, CE-IVD, limit of detection 0.2 ng/mL, catalog number RD191001100.

To calculate the homeostasis model assessment for insulin resistance (HOMA-IR) we applied the formula reported in the literature (8):

HOMA-IR = [insulin ($\mu U/mL$) *x* glucose *(mg/dL)*] / 405.

Markers for the metabolic syndrome were determined using the spectrophotometric method applied to each specific kit. HDL-chol was measured using the direct method (elimination/peroxidase), TG using the glycerol phosphate oxidase method and glucose using the glucose-6-phosphate dehydrogenase method.

We estimated the visceral adiposity per total body with the previous validated equations (9):

$$\text{Men: eVAI} = \left(\frac{\text{AC}}{39.68 + (1.88 \times \text{BMI})}\right) \times \left(\frac{\text{TG}}{1.03}\right) \times \left(\frac{1.31}{\text{HDL} - \text{chol}}\right)$$

$$\text{Women: eVAI} = \left(\frac{\text{AC}}{36.58 + (1.89 \times \text{BMI})}\right) \times \left(\frac{\text{TG}}{0.81}\right) \times \left(\frac{1.52}{\text{HDL} - \text{chol}}\right)$$

Normal values are 1 for both men and women, if they are non-obese and present normal adipose tissue distribution.

Statistical analysis

The database of all 104 patients was elaborated in *Microsoft Excel 2003 (Microsoft Corporation*, Redmond, WA, USA) and the statistics of the data was performed with *SPSS version 23.0* (IBM Corporation, Armonk, NY, USA). There were no missing data in our database. For each continuous variable we reported the mean ± standard deviation (SD), minimum value and maximum value. Categorical values were expressed as frequencies (percentages). One-way *ANOVA* and chi-square tests were applied for comparison of parameters between the group with MetS and the group without. Statistical power was calculated and presented as eta squared (η^2) for each

variable. In order to assess the presence/absence of correlations between variables and their strength, Pearson correlation was performed. A p value < 0.05 was considered statistically significant.

RESULTS

Characteristics of the study population divided in the 2 groups (with MetS and without MetS) are presented in first table. Our groups did not differ concerning age, gender, BMI or fat mass parameters, suggesting a good homogeneity and thus preserving possible bias at a minimum level. Regardless of no significant differences in percentages of adiposity, eVAI is significantly higher in patients with MetS, because of the variation of HDL, TG and WC.

Our study further investigated correlations between obesity parameters and adipokine levels, including their ratio and insulin values, alongside insulin resistance (tab. II).

*WC=waist circumference, HC=hip circumference, WHR=waist-hip-ratio, FM total=fat mass total, eVAI=estimated visceral adipose index, LAR=leptin-adiponectin-ratio.

Leptin levels present a strong and positive correlation with almost all obesity parameters evaluated, with or without MetS. A stronger association is reported in

the MetS group concerning leptin and fat mass (total, trunk, arms, legs), suggesting that in patients with MetS adipose tissue is associated with a higher stimulation of leptin secretion. Moderate to strong correlations are observed between LAR levels and all obesity parameters. These values do not vary significantly between groups.

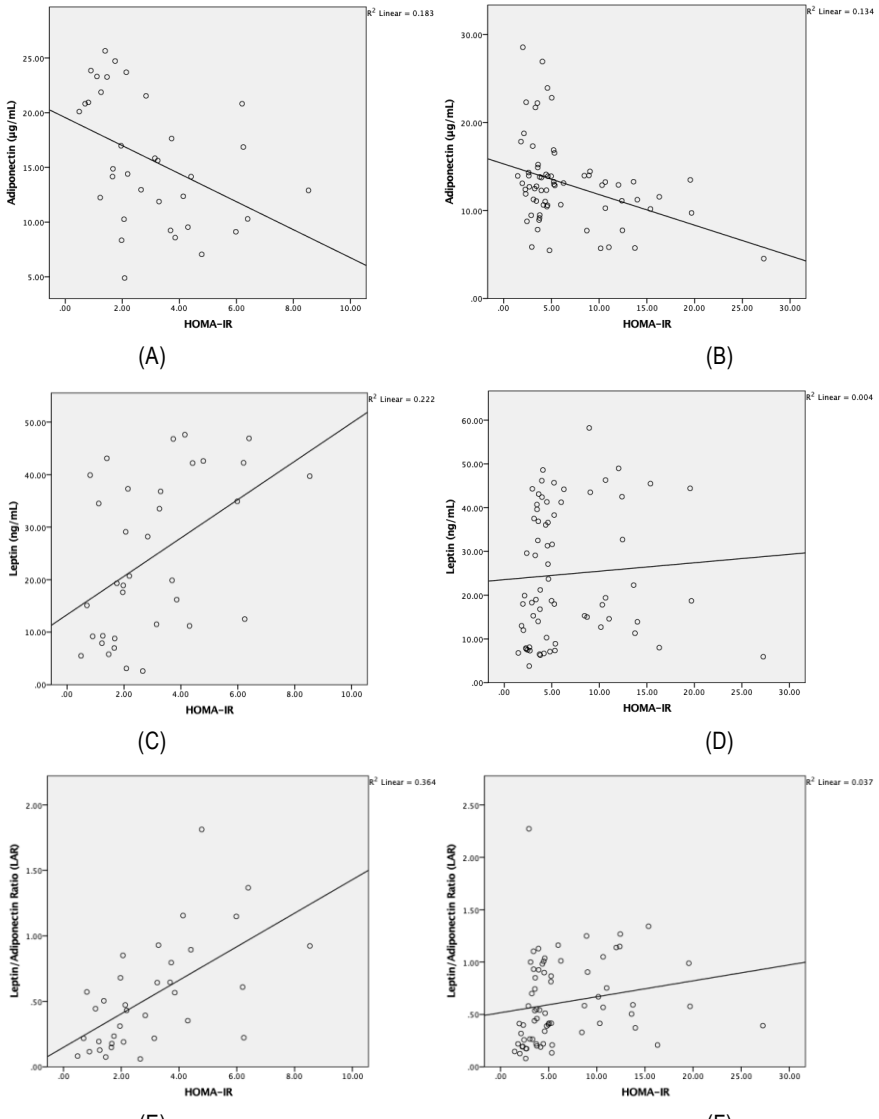

Fig. 1. Correlations between Adiponectin and HOMA-IR in (A) group without MetS (r=-0.428, p=0.01) and (B) group with MetS (r=-0.366, p=0.002); Correlations between Leptin and HOMA-IR in (C) group without MetS (r=0.471, p=0.004) and (D) group with MetS (r=0.066, p=0.592); Correlations between LAR and HOMA-IR in (E) group without MetS (r=0.604 p=<0.001) and (F) group with MetS (r=0.191, p=0.116).

In patients with MetS, insulin has higher values once the BMI is higher, but this does not seem to be associated with fat mass percentages of the whole body or of different areas of the body. At the same time, our results report moderate and positive correlations with fat mass expressed in kg and not percentages: trunk fat (kg) (r=0.369, p=0.029), left arm fat (kg) (r=0.504, p=0.002), right arm fat (kg) (r=0.496, p=0.002). In the other group, insulin is also associated only with fat mass expressed in kg: total fat (kg) (r=0.332, p=0.005), right arm fat (kg) (r=0.300, p=0.012), trunk fat (kg) (r=0.419, p<0.001).

In the group of patients without MetS adiponectin level is not associated with fat percentages in different areas of the body or total fat percentage, whereas in the group of patients with MetS adiponectin reports a weak and positive correlation between fat mass total, arms fat and legs fat percentages. Trunk fat percentage is not associated with adiponectin levels (p>0.05). Therefore, our study further analyzed the relationship between adipokines, and HOMA-IR. Adiponectin is negatively correlated with HOMA-IR and insulin in both groups, suggesting that insulin resistance is linked to the change in adiponectin levels (fig. 1).

Regarding biochemical parameters, glucose presents moderate correlations with HOMA-IR in the MetS group (r=0.563, p < 0.001) and in the group without MetS (r=0.521, p=0.001). Patients that present MetS also report an association between glucose and insulin (r=0.238, p=0.049) and between HDL and adiponectin (r=0.280, p=0.02).

DISCUSSION

Adiponectin levels differ statistically between the 2 groups, suggesting that the value decreases when MetS is present, even if patients present the same percentage of adipose tissue per total body and per different areas of the body. This result is supported by other studies from the literature that report a lower secretion rate of adiponectin in obesity-related diseases, including diabetes mellitus, dyslipidemia, hypertension or atherosclerotic cardiovascular disease (10-12). Recent reviews treat adiponectin as a potential therapeutic target for MetS, discussing drugs that increase plasma adiponectin (PPARγ agonists thiazolidinediones, phytochemicals, L-cys-teine), alongside their safety concerns and limitations (12-14). However, several clinical studies and a more recent meta-analysis report associations between high adiponectin and mortality (15-17). This adiponectin paradox seems to be characterized by adiponectin resistance, due to altered signal transduction and insulin sensitivity, as a consequence of T-cadherin hydrolysis (18-19).

In our cohort, adiponectin level correlates well with insulin resistance in both groups, while with body fat parameters the correlation is not present in the group without MetS. Having a very similar mean concerning the percentages of adipose tissue reported for specific areas of the body and even for the whole-body surface, these results suggest that insulin and insulin resistance are more relevant for adiponectin levels than obesity. Studies support our findings even though the entire mechanism of action of adiponectin is not yet known. When binding to its receptors AdipoR1 and AdipoR2, adiponectin activates adenosine monophosphate dependent kinase (AMPK), PPARγ and probably other signaling pathways that still need to be discovered (12, 20).

Leptin presents strong correlations with adipose tissue in both groups, reflecting an even stronger relationship in patients with MetS. Of all the areas analyzed, trunk area reports the strongest correlation, implying that abdominal adipose tissue plays a key role in leptin secretion.

Our study included the index calculated for visceral adipose tissue (eVAI), which did not correlate with adipokines or insulin. A paper on 5113 participants reports that ethnicity plays a role in establishing the cardiometabolic risk of patients and that in Europeans visceral adipose tissue (measured by ultrasonography) showed stronger positive associations with most of the cardiometabolic risk factors than subcutaneous fat (21). However, another recent study on samples of abdominal adipose tissue obtained from both subcutaneous and visceral fat depots show that adipokine dysregulation is first seen in subcutaneous adipose tissue, rather than in visceral adipose tissue. This conclusion suggests that endocrine dysfunction in the subcutaneous adipose tissue may represent an early risk sign of MetS (22).

Results from our analysis present LAR as a parameter with a direct proportional relationship with fat mass, regardless of the body surface area studied. The correlations are always stronger in patients with MetS, but not as strong as leptin alone. Although LAR levels are higher in patients with MetS, the difference between the 2 groups is not statistically significant, possibly because of the similar leptin values between the 2 groups. Even though adiponectin values differ significantly, leptin presents a stronger correlation and therefore weights more in the ratio between the 2. In the literature, high LARs report a higher risk of developing type 2 diabetes mellitus (23). Also, in a study with a 2.8-year follow-up timeframe, LAR had a better predictive value than adiponectin alone for the regression of MetS, suggesting that LAR may be used as a clinical marker for the management of MetS (24).

HOMA-IR is shown to correlate best with adiponectin in patients with MetS and with LAR in patients without MetS. Leptin and LAR do not correlate with insulin resistance in patients with MetS, but it is important to highlight those only patients with no known metabolic or cardiovascular disease were included in this study. There are some patients with high glucose values, but they are not confirmed with diabetes. Therefore, this can explain the lack of association between LAR and HOMA-IR in patients with MetS.

Several studies reported a positive correlation between adiponectin and HDL (25-28), similar to our findings in the study. Adiponectin is an antiatherogenic adipokine, with an important role in prevention. It has been demonstrated that hypoadiponectinemia is an effective predictor for decreased cholesterol efflux capacity (a measure of HDL quality and quantity) in adults, regardless of the obesity status or degree (29).

CONCLUSIONS

Patients with MetS that did not follow prior treatment for any chronic disease and are characterized by similar adipose tissue percentage and distribution, report the following: lower adiponectin levels than patients without MetS, but still a positive association with HDL; no modification in leptin levels compared to patients without MetS; negative correlation between adiponectin and insulin resistance; strong association between leptin and adipose tissue mass.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

COMPUTER VISION SYNDROME IN MEDICAL STUDENTS AND HEALTHCARE WORKERS (Abstract). The present study aims to open a new perspective about Computer Vision Syndrome in medical students and healthcare workers. This work aims to analyze whether there are any differences in ophthalmological and musculoskeletal symptoms between occupational groups. **Material and methods:** In this study were included 407 participants from different occupational groups: students, doctors, nurses, pharmacists and university teachers All participants completed a specially designed questionnaire (CVS-F3) via Google Forms**. Results:** The frequency of female participants was higher (68.1% *vs.* 31.9%). The most common ophthalmological symptoms encountered in students were dry eyes (73.3%), focusing difficulties (72%) and eye fatigue (69.3). The most common ophthalmological symptoms encountered in doctors were discomfort at near vision (48.3%) and blurred vision (24.4%), in nurse blurred vision (5.6%), in pharmacists focusing difficulties (5.6%) and in university teachers focusing difficulties (2.8%). The most frequently encountered Musculo-skeletal symptoms, regardless of profession, were neck, shoulder, and back pain. The number of hours spent during the day or at night correlated significantly with age and the most used electronic device was smartphone. **Conclusions:** The ophthalmic symptoms are different depending on the medical category. Instead, the musculoskeletal symptoms most often encountered in all medical categories were neck, shoulder and back pain. **Keywords:** COMPUTER VISION SYNDROME, VIDEO DISPLAY TERMINALS, MEDICAL STUDENTS, DOCTORS, NURSES.

The aim of the present study is to analyze the relationship between Computer Vision Syndrome (CVS) and exposure to various types of gadgets in healthcare workers and medical students. Moreover, this work aims to analyze whether there are differences between occupational groups.

According to the Sixth European Working Conditions Survey (Eurofound, 2017), more than half of European workers use various gadgets such as laptops, computers, tablets or smartphones at work. The economic sectors with the most widespread use of gadgets are financial services, public administration, education and health (1).

Due to the SARS-CoV-2 pandemic, the use of gadgets in healthcare has increased substantially due to online work. Worldwide, online consultations using various electronic devices with digital screens have been promoted to avoid face-to-face contact (2).

Computer Vision Syndrome represents a series of eye, musculoskeletal and behavioral conditions caused by prolonged use of digital screen devices. The first symptoms that appear are headaches, blurred vision, red eyes, neck and back muscle pain, eye fatigue, visual accommodation difficulties and attention disorders (3).

Blehm *et al.* classified CVS into four categories:

• The first category is CVS associated with asthenopia, which includes symptoms of eye fatigue, irritated, red, and dry eyes.

• The second category is CVS associated with changes in the ocular surface and includes dryness, burning sensation and feeling of foreign body in the eyes.

• The third category is CVS associated with visual disturbances and includes symptoms such as blurred vision, diplopia, focusing difficulties and presbyopia.

• The fourth category are extraocular symptoms, mainly shoulder, neck and back pain (4).

MATERIAL AND METHODS

We conducted a cross-sectional study, which included 407 participants, as follows: Students in "Grigore T. Popa" University of Medicine and Pharmacy from Iasi; Doctors; Nurses; Pharmacists and Teaching staff of "Grigore T. Popa" University of Medicine and Pharmacy from Iasi.

The study took place between December 2021 and March 2022. All participants completed a specially designed questionnaire (CVS-F3) via Google Forms. Each participant read and signed the "Informed Consent" certifying the agreement to participate in the study and to consent to the publication of the results, for scientific purposes and under the total protection of anonymity. Prior to patient enrollment, the study protocol was approved by the Research Ethics Committee of the "Grigore T. Popa" University of Medicine and Pharmacy from Iasi.

The data were systematized and centralized in an *SPSS 18.0* database and were processed with the statistical functions to which they lend themselves. Confidence intervals at the 95% significance threshold were used in the data presentation.

For the descriptive statistical analysis, the ANOVA test was used, which highlighted the following indicators:

• primary indicators: minimum, maximum, frequency:

• average value indicators: simple arithmetic mean, median;

• dispersion indicators: standard deviation, standard error, CI of the mean;

• the Skewness test ($-2 < p < 2$) validates the normality of the series of values, it is used when the examined variable has continuous values.

RESULTS

Of the total subjects (n=407), 71.7% were students at University of Medicine and Pharmacy Grigore T. Popa, Iasi, 4.2% were pharmacists, 20.6% doctors, 3.2% nurses. From the total doctors, 2.5% were also university teachers at "Grigore T. Popa" University of Medicine and Pharmacy from Iasi.

The series of values for age was homogeneous, which suggests that statistical significance tests can be applied: variations in the range of 18-66 years, group average 29.25 years ± 11.36, median 24 years, the result of the Skewness test $p = 1.423$ (tab. I).

The frequency of female participants was higher (68.1% vs 31.9%). Over 68% of the participants had been using electronic devices for over 5 years. Comparing by gender, it is noted that 70.8% of men and

66.8% of women used gadgets for over 5 years (p=0.125).

TABLE I .
Descriptive data regarding age (years)

		Study group
N		407
Mean		29.25
Median		24
Standard deviation		11.36
Variance		38.84
Skewness Test		1.423
Er. standard Skewness		0.121
Minimum		18
Maximum		66
Percentile	25	22
	50	24
	75	31

Of the total subjects (n=407), 292 (71.7%) were students, predominantly female (64.7% vs 35.3%; p=0.019). From the total students, 44 .5% were studying general medicine, 39.1% nursing, 7% dentistry, 4.7% pharmacy, and 44.3% of them being in the years 2-3 of study.

The total number of hours spent on electronic devices did not correlate significantly with age (r= -0.079; p=0.113), but the number of hours spent during the day or at night correlated significantly with age, highlighting the fact that older people use electronics devices more hours during the day (r= 0.110; p=0.026), and younger people use gadgets more hours at night (r= -0.242; p=0.001) (fig.1).

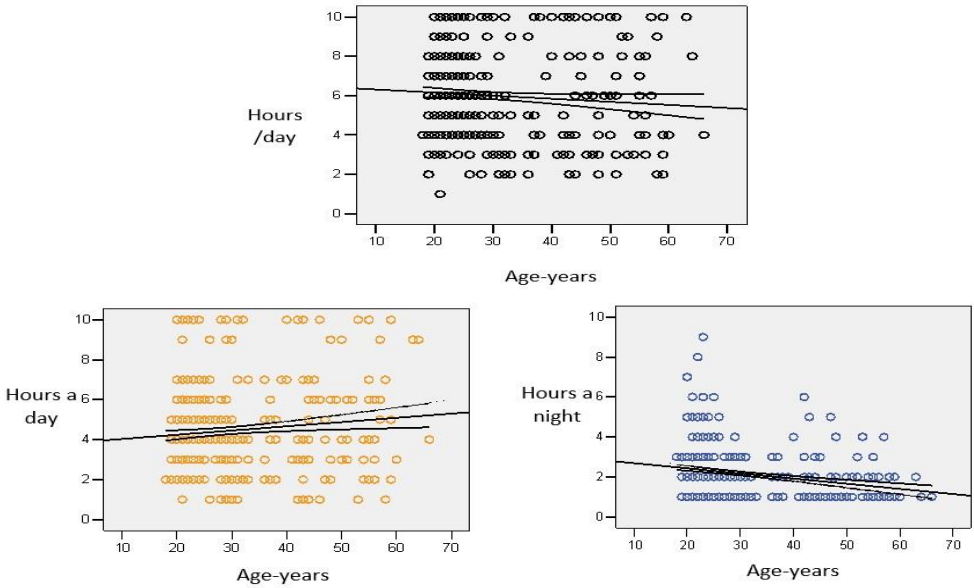

Fig. 1. Correlation of age with time spent on electronic devices

In our study, the most used electronic device was smartphone (83.8%), followed by laptop (78.4%), computer (21.4%) and tablet (17.4%). Regardless of the device, the daily usage time was 5-8 hours. From the total of participant, 88.2% stated that the hours spent using the gadgets are interrupted, and only 11.8% spent continuously

hours using gadgets.

Of the 214 subjects (52.6%) who wear glasses (71%) were female and 102 (47.7%) changed diopters in the last 12 months. Of the total 407 participants, 65.4% of students, 24.3% of doctors, 4.7% of pharmacists and 2.8% of nurses wore glasses. Only 3.9% of students wore contact lenses.

Myopia was the most common refractive error, being found in 37.1% of students, 33.3% of doctors, 35.3% of pharmacists and 38.5% in nurses (fig. 2).

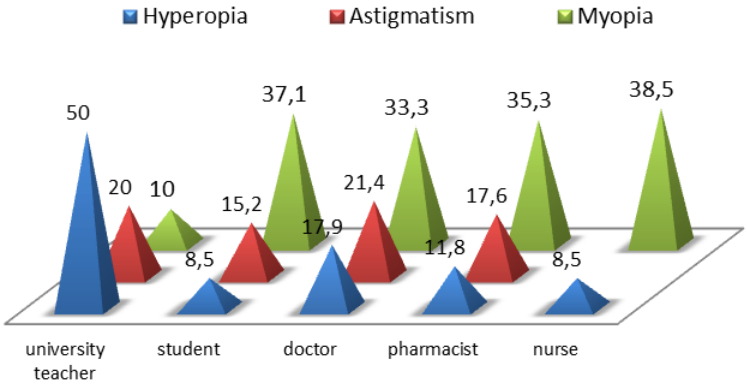

Fig. 2. Frequency of refractive errors according to profession

With the exception of smartphone, where the degree of illumination of the screen was most often between 50-70%, in the other types of gadgets, the degree of illumination of the screen was most often 10-40% (fig.3).

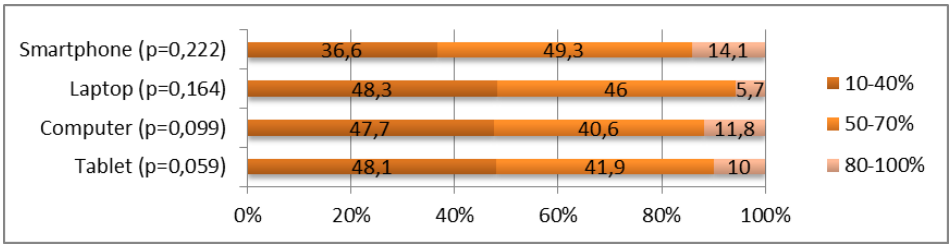

Fig. 3. Frequency of gadgets used according to screen lightning

Of the total study participants, 47.66% declared that they use artificial light at the office while using gadgets, and 52.33% declared that they use natural light, the percentage difference being minor. Of the 407 participants, 20.3% declared that they suffer from dry eyes, and they use artificial tears.

The most common ophthalmological symptoms encountered in students were dry eyes (73.3%), focusing difficulties (72%) and eye fatigue (69.3) (fig.4). The most common ophthalmological symptoms encountered in doctors were discomfort at near vision (48.3%) and blurred vision (24.4%), in nurse blurred vision (5.6%), in pharmacists focusing difficulties (5.6%) and in university teachers focusing difficulties (2.8%) (fig. 4).

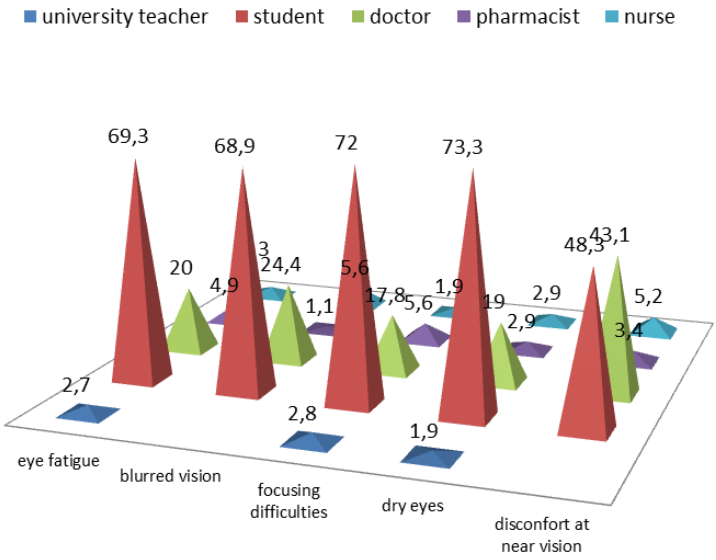

Fig. 4. Frequency of ophthalmological symptoms according to profession

The most frequently encountered musculoskeletal symptoms, regardless of profession, were neck, shoulder, and back pain.

Depending on the profession, there is an awareness of the fact that prolonged use of gadgets can affect health and lifestyle: 80.9% of students, 79.8% of doctors, 84.6% of nurses, 88.2% of pharmacists and 90% of university teachers believe that gadgets affect their health and lifestyle and 83.3% of total participants are willing to reduce the number of hours spent in front of gadgets.

DISCUSSION

Very few published studies have analyzed the effects of exposure to various gadgets on the visual system of healthcare workers. A North American study conducted on 380 radiologists who used computers at work estimated a prevalence of eye strain of 36% (5). Other hospital-based studies either focused on a sample of caregivers and computer operators (6) or did not specify whether their sample consisted of healthcare workers (7,8). However, a review of the literature concluded that the occurrence of CVS should be considered in doctors, nurses and other healthcare workers due to the use of tablets and laptops in hospitals (9).

A study conducted in 2021 on 382 students revealed that 63.5% of participants have been using gadgets for over 4 years (10). This data is similar to the results of our study where over 68% of participants have been using electronic devices for over 5 years. The results of the same study show that the most used gadget is the smartphone 71% of the participants (10), these results being similar to those of the present study in which the most used gadget was also the smartphone, being used by 341 participants.

The results of a study conducted on 100 medical students showed that the most common symptoms associated with pro-

longed use of gadgets were dry eyes, blurred vision, and pain in the neck, shoulders and back (11). The most common symptoms associated with Computer Vison Syndrome reported in another study of 80 medical students were headache in 50% of participants and dry eye in 45% of them (12). These data are similar to our research where the most common symptoms associated with gadget use were dry eyes found in 73.3% of students, blurred vision in 68.9%, and neck, shoulder and back pain were declared by 65.2% of the students.

The same study mentioned earlier showed that only 13% of college students use gadgets during the day, and 87% of them said they use gadgets during the night (11). These data are similar to the results of our study in which the number of hours spent during the day or at night correlated significantly with age, highlighting the fact that older people use electronic devices more hours during the day ($r= 0.110$; $p=0.026$), and younger people use gadgets more hours at night ($r= -0.242$; $p=0.001$).

A 2022 study that analyzed the effects of prolonged gadget use on physical and mental health among healthcare workers found that the longer the time spent working in front of electronic devices with digital screens, the greater the risk of muscle pain, headaches and stress at work. The results of the study showed that it is important to reduce the daily exposure to gadgets for doctors and nurses (13). Another 2022 study found a high prevalence of CVS among healthcare workers (14). In our study, 79.8% of doctors and 84.6% of nurses believe that digital screens affect their health and lifestyle.

Another study conducted in 2022 that evaluated the frequency and determinants of CVS among radiologists in Saudi Arabia showed that the most common symptoms perceived by the participants were headache (72.1%), dry eye (70.7%), eye burning sensation (63.7%) and blurred vision (56.3%) (15). These results are similar to those in the present study where doctors reported that the most common eye symptoms were near vision discomfort (48.3%), blurred vision (24.4%), eye fatigue (20%) and dry eye (19%).

In our study, 65.4% of students, 24.3% of doctors, 4.7% of pharmacists and 2.8% of assistants wore glasses. Only 3.9% of students wore contact lenses. These data are similar to those in the study conducted by Iqbal et al. in which 72% of students wore glasses or contact lenses (16).

Several studies have demonstrated the health disadvantages of CVS, highlighting the fact that prolonged use of gadgets causes visual disturbances, nervousness, irritability and fatigue. This will determine a decrease in the ability to concentrate and work time, even leading to a lack of interest in personal life. Because of these negative effects, studies have suggested that special campaigns in schools, universities and media are particularly important to inform the public about the risks and disadvantages of CVS on health, work and lifestyle (17-23).

In our study, 80.9% of students, 79.8% of doctors, 84.6% of nurses, 88.2% of pharmacists and 90% of university teachers believe that digital screens affect their health and lifestyle. Of the 407 participants, 83.3% are willing to reduce the number of hours spent in front of gadgets. These percentages are higher than those in the study conducted by Gammoh which showed that 69.2% of students believe that gadgets affect their health and quality of life, and only 59.2% are willing to reduce

their time using gadgets (10), the results of our study being therefore more satisfactory.

The most effective way to prevent CVS is to develop health programs that should support a healthy lifestyle (stretching exercises, smoking cessation and adequate sleep time/quality) and to increase workers' awareness of the ergonomics of their workstation (adjustment of chair height, desktop height, keyboard and mouse arrangement, screen contrast and brightness and viewing distance) (24-26).

Several limitations should be considered when interpreting the results from our work. All participants were from different healthcare branches, so the study results may not be generalizable. Moreover, relevant information about video display terminals (VDT) working time was obtained through self-answered questionnaires, which are not always reliable. Further larger-scale studies are needed to address the effect of VDT use on CVS in medical students and healthcare workers and provide guidance regarding good working practices.

CONCLUSIONS

In the present study, the number of hours spent during the day or at night were significantly correlated with age, highlighting the fact that older people use electronic devices more hours during the day, and younger people use gadgets more hours at night.

The most common ophthalmological symptoms encountered in students were dry eyes, focusing difficulties and eye fatigue. The most common ophthalmological symptoms encountered in doctors were discomfort at near vision and blurred vision, in nurse blurred vision, in pharmacists focusing difficulties and in university teachers focusing difficulties, demonstrating that ophthalmic symptoms are different depending on the medical category. Instead, the musculoskeletal symptoms most often encountered in all medical categories were neck, shoulder and back pain.

Depending on the profession, there is an awareness of the fact that the use of electronic devices for a long time affects health and lifestyle, and the vast majority of participants are willing to reduce the number of hours spent in front of gadgets, thus highlighting the fact that regardless of the category in which found, the participants of the present study are aware of the negative effects caused by Computer Vision Syndrome and want to improve their quality of life by using gadgets for a shorter time.

THE TIME FOR SURGERY IN THYROID NODULES (Abstract): The aim of the study was to improve the diagnosis and surgical treatment of thyroid nodules. **Material and methods:** During 2012-2022, a serial, retrospective and prospective clinical study was conducted on 124 patients, with clinically unresponsive thyroid nodules, with/without signs of compression on adjacent structures, and/or with suspected ultrasonographic, scintigraphic, cytological malignancy. **Results:** Depending on the hyperplastic (goiter), tumor (adenoma, carcinoma), or autoimmune etiology of nodules, surgical treatment consisted of total and subtotal thyroidectomies, unilateral hemithyroidectomies, nodules enucleation, isthmectomies, combined - unilateral hemithyroid-ectomies and enucleation of the nodule or partial contralateral lobe resections and total thyroidectomy with lymphadenectomy. In 82 patients was performed frozen section for intraoperative diagnosis of malignancy and establishing the definitive volume of thyroidectomies. Complications of the intra- and postoperative period were not determined, except for one patient who developed transient paresis of a recurrent laryngeal nerve due to posttraumatic edema in the early postoperative period, with complete recovery after one month. The relapse of pathology was not identified. **Conclusions:** Once detected, thyroid nodules require clinical and imaging surveillance regardless of nodule size. Surgical treatment is indicated for nodules with clinical and paraclinical signs of malignancy, refractory to conservative treatment, and those associated with compression signs. The time for surgery should be decided in common with endocrinologists, family physicians, and other specialists in every suspicious case. **Keywords:** THYROID NODULES, SURGICAL TREATMENT.

Thyroid nodules are discrete lesions of thyroid gland parenchyma and morphologically can denote the hypertrophic form of autoimmune thyroiditis, cysts, oncocytic, follicular, or colloid adenomas and carcinomas of the thyroid gland (1, 2). Thyroid nodules are frequent occurrences in the general population and may be detected up to 76% by imaging methods. They are found four times more in women than in men, and their prevalence increases with age and body weight (3, 4).

The main clinical concern about thyroid nodules is malignant potential, causing compressive symptoms or/and thyroid dysfunction (5).

Exposure to ionizing radiation and endemic iodine deficiency are the important factors that persist in the Republic of Moldova, and other states of Eastern Europe and influence the thyroid nodule's tumorigenesis. In 1985, the morbidity index for thyroid

gland cancer was 1.35 new cases per 100,000 population annually, and after the Chernobyl accident, it continuously increased, in 2019 reaching 8.3 new cases per 100,000 population (6). In the last 10-15 years there are 8-10 times increase in the incidence of endemic diseases of the thyroid gland (7). Iodine deficiency induces a lack of synthesis of thyroid hormones with nodular hypertrophy of the thyroid gland and consequently an increase in the risk of malignancy. Follicular and undifferentiated thyroid carcinomas are more related to iodine deficiency, meanwhile, papillary thyroid cancer has significantly increased following the Chernobyl disaster (8).

For the last 30 years were published thousands of articles, books, and guidelines from different clinics and international Associations of Thyreology about the diagnosis and treatment of thyroid nodules. Due to the multidisciplinary of the problem regarding endocrinology, nuclear medicine, imaging, surgery, and oncology no unique consensus on the management of thyroid nodules was decided. In this context, every clinician concerned about patients with thyroid nodules should decide on better management for each patient according to guidelines recommendations, the presence of risk factors, and the particular evolution of the disease.

MATERIAL AND METHODS

In the clinic of the Department of Surgery no. 5 of SUMPh "N. Testemitanu", Chisinau, Republic of Moldova, during 2012-2022, a serial, retrospective, and prospective clinical study was conducted on 124 patients, with clinical and paraclinical signs of thyroid nodules. The patients included in the study, according to the inclusion criteria, previously signed informed consent.

In the first stage, all patients were examined clinically and paraclinical through standard investigations - complete blood count test, biochemical blood test, coagulogram, blood type, and Rh-factor, rapid plasma reagin, urinalysis, electrocardiogram, and chest X-rays.

The patients were examined by thyroid ultrasound. The sonographic appearance of thyroid nodules was described according to their site, size, shape, composition, echogenicity, edges, presence of calcifications, and lymphadenopathy, which were systematized into TI-RADS (Thyroid Imaging Reporting and Data System) categories: TI-RADS 1 – normal thyroid gland; TI-RADS 2 – benign nodules; TI-RADS 3 – probably benign nodules; TI-RADS 4 – highly suspicious nodules; TI-RADS 5 - probably malignant nodules. Dopplerography and son elastography have supplemented the informativeness of ultrasound in assessing the type of vascularization and, respectively, the degree of elasticity of the thyroid nodules.

In the assessment of thyroid function and nodule functional autonomy were measured total or free serum concentrations of thyroxine FT_4/T_4 and triiodothyronine FT_3/T_3, as well, were performed Technetium 99m pertechnetate thyroid scan, also were estimated markers of autoimmunity - anti-TPO (anti-thyroperoxidase), anti-TG (anti-thyroglobulin) antibodies and the tumor marker – calcitonin.

The cytological diagnosis of thyroid nodules was obtained in 53 cases by FNAB – Fine Needle Aspiration Biopsy, being reported to the Bethesda system: I – non-diagnostic or unsatisfactory; II – benign; III – atypia of undetermined significance or follicular lesion of undetermined significance; IV – follicular neoplasm or suspi-

cious for a follicular neoplasm; V – suspicious for malignancy; VI – malignant.

In addition, a frozen section was performed intraoperatively in 82 patients, for diagnosis of malignant thyroid nodules with the decision on the volume of thyroidectomies.

Based on the postoperative histological confirmation of thyroid nodules were decided the subsequent tactic and follow-up of patients in the postoperative period and served in the interpretation of pre- and intraoperative clinical and paraclinical results to establish criteria of malignancy.

The results were processed and analyzed using statistical IBM Corporation, SPSS software version 26.0. The mean, absolute and relative values, and the association coefficient were measured. Statistical Pearson's chi-square test and Fisher's exact test were applied. The p-value < 0.05 was accepted as statistically significant.

RESULTS

The obtained data revealed that thyroid nodules were detected predominantly in women 83.9% (n=104), in a ratio of 5:1 compared to men 16.1% (n=20). The age of the patients included in the study ranged from 19 to 71 years, with an average of 47.55 years among women and 42.85 years among men.

The complaints reported by the patients were: discomfort/pain while swallowing (96.0%), globus sensation ("lump in the throat") (85.5%), fatigue (72.6%), the presence of a lump in the anterior cervical region (60.5%), excitability and emotional lability (44.4%), palpitations (34.7%), dyspnea (16.1%), tremors (12.1%), sweating (8.9%), weight loss (4.0 %), dysphonia (3.2%).

All the patients were on evidence at the family physician or/and endocrinologist, from which 13.7% did not follow conservative treatment, due to the rapid increase in the size of the nodular lump and the high suspicion of malignancy, 83.9% did not obtain disease remission, despite the administered treatment, 1.6% had contralateral recurrence after hemithyroidectomy and 0.8% - ipsilateral recurrence after subtotal lobectomy (the last cases had surgeries in other clinics). 75 (60.48%) patients presented with a solitary nodule, and 49 (39.51%) with multinodular goiters. The average duration of the disease was 47.13 months, which means approximately 4 years, with a minimum of one month and a maximum of 10 years.

According to the serum levels of thyroid hormones and TSH, 92.7% of patients were euthyroid, 5.6% - hyperthyroid, and 1.6% - were hypothyroid. Autoimmune etiology (Hashimoto's Thyroiditis) of nodular goiters was confirmed by elevated Anti-TPO values and ranged from 170 IU/ml to 1140 IU/ml. Anti-TG and thyroglobulin levels did not correlate with the detected nodules, being clinically insignificant. In three cases calcitonin values exceeded the reference range (165.0 - 585.0 pg/ml) and were associated with follicular adenoma, oncocytic cell carcinoma, and papillary carcinoma, which excluded affinity to a certain malignant process.

The ultrasound size of thyroid nodules ranged from 0.8 cm to 6.0 cm, with a mean size of 2.41 cm. More affected was the right lobe in 35.5% of cases, compared to bilateral lesions at 29.8%, left lobe – at 29.0%, and isthmus - at 5.6%. By composition, mixed echoic nodules (with solid and fluid components) predominated in 64.5%, followed by solid ones in 30.6% of cases. Most nodules showed isoechogenicity

(41.9%) and hypo echogenicity (37.1%). The shape of the nodules "taller than wide" was detected only in 8.9%, irregular edges in 14.5%, and the presence of calcifications in 15.3%. Laterocervical lymphadenopathy was visualized sonographically in 8.1% but was confirmed intraoperatively only in one case (0.8%). Dopplerography showed mixed vascularization in 42.7% of examined nodules. In sonoelastography, 74.2% of nodules were distinguished by elastic tissue, and 16.9% with stiffness. Table I shows the thyroid nodule size and its correlation with malignancy.

TABLE I

Thyroid nodules size and correlation with malignancy

Nodules size	Frequency	Valid Percent	Malignant nodules frequency	Malignant nodules valid percent
0,8-1,9	56	45.2	9	40.9
2,0-2,9	32	25.8	5	22.7
3,0-3,9	20	16.1	6	27.3
4,0-4,9	11	8.9	2	9.1
5,0-6,0	5	4.0	-	-
Total	124	100.0	22	100.0

On scintigraphy, thyroid nodules were norm functional (warm) in 6.5% of cases, hypofunctional (cold) in 74.2% of cases, and hyper functional (hot) in 8.9% of cases. In 3.2% of cases, the thyroid scan was not informative because the nodules were situated posterior, and in multinodular goiters, some of the ultrasound nodules <1.0 cm were not detected.

FNAB was performed for nodules ≥1.0 cm, both solitary and those dominant in unilateral multinodular goiters. Cytologically tested nodules were included in a greater proportion in Bethesda categories II, III, and IV as shown in table II. It should be noted that, in 6 situations, the patients categorically refused to perform FNAB, due to the risk of complications.

TABLE II

Thyroid nodules cytology and correlation with malignancy

FNAB categories	Frequency	Valid Percent	Malignant nodules frequency	Malignant nodules valid percent
Bethesda I	2	3.77	-	
Bethesda II	17	32.1	4	33.3
Bethesda III	14	26.41	2	16.7
Bethesda IV	11	20.75	3	25.0
Bethesda V	8	15.1	2	16.7
Bethesda VI	1	1.87	1	8.3
Total	53	100.0	12	100.0

Indications for surgical treatment were nodules with suspicion of clinical and paraclinical malignancy, nodules continuously growing despite thyroid suppression treatment, cold nodules with hypervascularization and/or stiffness, nodular or multinodular goiters with signs of compression or with several nodules ≥ 1.0 cm, nodules or nodular goiter associated with hyperthyroidism.

The volume of thyroidectomies was decided according to patient consent and age, international guidelines recommendations, uni- or bilateral thyroid lesions, and intraoperatively results of frozen section. In 16 cases cancer was confirmed by frozen section and we extended for total thyroidectomy. The structure of performed surgeries is unfolded in table III.

Thyroidectomies were performed within the limits of healthy tissues, highlighting and respecting the adjacent anatomical structures, especially the recurrent laryngeal nerve, parathyroid glands, and trachea.

TABLE III
Type of surgery performed in the study

Surgical procedure	Frequency	Valid Percent
Hemithyroidectomy	72	58.1
Subtotal thyroidectomy	5	4.0
Total thyroidectomy	28	22.6
Isthmectomy	3	2.4
Enucleation of nodule	3	2.4
Combined	11	8.9
Reoperation	1	0.8
Thyroidectomy with lymphadenectomy	1	0.8
Total	124	100.0

Postoperatively the histopathology confirmed: Goiter - 43 cases (34.7%), Papillary carcinoma - 8 cases (6.5%), Follicular carcinoma - 10 cases (8.1%), Papillary – follicular (mixed) carcinoma - 3 cases (2.4%), Oncocytic carcinoma - 1 case (0.8%), Follicular adenoma - 56 cases (45.2%), Papillary adenoma - 1 case (0.8%), Oncocytic adenoma - 2 cases (1.6%). Thyroid carcinoma was detected in 22 cases (17.74%).

The postoperative period in all patients was favorable. The average length of stay in the hospital was 6.95 days. One of the early postoperative complications that occurred was temporary dysphonia in a patient after total thyroidectomy, caused by posttraumatic edema, which recovered completely within one month. Other early and late postoperative complications were not recorded. Thyroid hormone replacement therapy was individually corrected by endocrinologists according to serum values. Patients were monitored at an interval of 1, 3, 6, 12, and 24 months. A relapse of the pathology was not detected.

DISCUSSION

Thyroid nodules, according to the literature data, have a low malignancy rate of 5 - 15%, but due to the high prevalence in the general population, they require a conscientious approach. (1,2,4,5).

In the evaluation of thyroid nodules, the main keys are the measurements of serum TSH, ultrasonography of the thyroid gland, and FNAB (1,2,5). American Thyroid Association (ATA), American Association of Clinical Endocrinologists (AACE), American College of Endocrinology (ACE), and Associazione Medici Endocrinology (AME) recommend scintigraphy only in cases of low TSH (9,10). In our study, 92.7% of patients with thyroid nodules were euthyroid with a normal TSH and the use of scintigraphy was important for the detection of "cold" nodules, which were associated with a high risk of malignancy, as well as for determining the functional autonomy of the nodules.

TIRADS ultrasonographic criteria (ACR-TIRADS, EU-TIRADS, K-TIRADS, C-TIRADS) are sometimes not sufficient to establish the malignant potential of nodules because not all thyroid cancers have the same image. In addition to ultrasound, dopplerography and sonoelastography can be performed, which provide high informativeness, as we mentioned in the study results, sometimes equivalent to the cytological examination. In this way, invasive diagnostic procedures in long-term monitoring can be avoided (11).

Another side of the problem in the diagnosis of thyroid nodules is performing FNAB. Although in most studies cytological examination showed promising results, there are two main limitations – indeterminate cytology and inadequate specimen. The sampling of qualitative cytological material, to reduce the false negative rate requires scoring the solid areas of the nodules (12). Bethesda categories III and IV are considered indeterminate due to diagnostic errors and sometimes exceeding the moment of organ-preserving surgery (13). Furthermore, FNAB is recommended as a follow-up tool for benign nodules, but no guideline indicates the deadline for performing a biopsy of benign nodules and a certain landmark when a patient should be subjected to surgery. In a long-term surveillance of nodules and persistence of proliferative stimuli of the thyroid gland multinodularity may appear (14,16). More recent studies describe the states of discomfort, stress, and anxiety associated with repeating FNAB and the risk of complications (hematomas, dissemination of the process) (15).

The intraoperative frozen section is a valuable diagnostic test (12). In our study, it was important in the diagnosis of malignant nodules, especially with indeterminate cytology, in the decision on the volume of thyroidectomies, for solving cases in a single surgical procedure, avoiding reoperation and repeated anesthetic risk.

The diagnosis and treatment of thyroid nodules require close collaboration between different specialists, and it has to be mentioned that any suspicious malignancy case should be subjected to surgery. The increase in time for surgery may worsen the evolution and even survival of patients with low-risk thyroid cancer.

CONCLUSIONS

Thyroid nodules are clinically important due to their malignant potential, the degree of compression on adjacent structures, and the dysfunction of the thyroid gland. Once detected, thyroid nodules require clinical

and imaging surveillance regardless of nodule size.

Surgical treatment is indicated for nodules with clinical and paraclinical signs of malignancy, refractory to conservative treatment, and those associated with compression signs. The time for surgery should be decided in common with endocrinologists, family physicians, and other specialists in every suspicious case.

CONFLICT OF INTEREST AND FUNDING

The authors declare no conflict of interest, and they received no funding regarding this scientific research.

NEWS

IS CANNABIS A POTENTIAL TREATMENT FOR OBESITY AND ASSOCIATED PATHOLOGIES?

Few and often under-effective drugs are available to address the increasing prevalence of obesity and type 2 diabetes. Glucagon-like peptide 1 receptor (GLP-1R) agonists improve glycemic control but have suboptimal efficacy against adiposity and insulin resistance. Recently developed peripherally restricted CB1R inhibitors, overcome these safety issues, while drastically lowering body weight in obese animal models. These compounds may also improve specific metabolic systemic and tissue complications, including insulin and leptin resistance, dyslipidemia, nonalcoholic fatty liver disease, inflammation, β-cell loss, and diabetic nephropathy. In particular, GLP-1 secretion is modulated by changes in CB1R signaling, while insulinotropic action of GLP-1R agonism is enhanced in CB1R-deficient mice, suggesting the existence of reciprocal functional interactions between GLP-1R and CB1R. Obesity is a heterogeneous disease that requires pharmacological approaches capable of targeting several pathways. GLP-1R-based unimolecular multiagonists that affect multiple metabolic targets have exceptional preclinical efficacy and are being investigated in more and more clinical trials. Chemical coupling of these newly developed molecules with an increasing number of peripheral CB1R inhibitors may have a major impact on the pharmacotherapy of obesity and diabetes, an interesting prospect given the structural and functional plasticity of CB1R and the emergence of new generations of peripheral “fusioned” CB1R inhibitors (Zizzari P, He R, Falk S, *et al.* CB1 and GLP-1 Receptors Cross Talk Provides New Therapies for Obesity. *Diabetes*, 20121; 70(2): 415-422 / doi.org/10.2337/db20-0162).

ZINC POTENTIATES THE ANTIOXIDANT EFFECT OF DAPAGLIFLOZIN IN RATS WITH EXPERIMENTAL-INDUCED DIABETES

ZINC POTENTIATES THE ANTIOXIDANT EFFECT OF DAPAGLIFLOZIN IN RATS WITH EXPERIMENTAL-INDUCED DIABETES (Abstract). Diabetes mellitus (DM) is a multifaceted disorder that disrupts the body's overall metabolic equilibrium, giving rise to various organ-related complications such as cardiovascular, neuronal, and renal problems. In this research, we **aimed** to investigate the effects of zinc chloride (Zn), dapagliflozin (DAPA) and their combination on some biochemical parameters evaluating the liver function, lipid metabolism and cellular oxidative processes in rats with streptozotocin-induced diabetes. **Material and methods:** The rats were distributed into five groups (of five animals each): Control: citrate buffer; STZ and fat diet; STZ+Zn and fat diet; STZ+DAPA and fat diet; STZ+DAPA+Zn and fat diet. DM was induced in rats by intraperitoneal administration of a single daily dose of streptozotocin (STZ) of 20 mg/ kg body weight (kbw), for three consecutive days, and fat diet (10 g cholesterol/100 g diet) for 4 weeks. Citrate buffer (0.1 mL/100 g body) was intraperitoneal administered to the control rats. DAPA 1 mg/kbw, and Zn 5 mg/kbw were administered orally as a single daily dose for 4 weeks. **Results:** The treatment with Zn, DAPA and their combination resulted in weight loss and a decrease in blood glucose level, the higher effect being evidenced in STZ+Dapa+Zn group. The use of Zn, DAPA and Zn+DAPA in STZ-induced DM in rats with fat diet led to a decrease in blood values of transaminases, total cholesterol, triglycerides and in malondialdehyde activity, most substantially in the group treated with DAPA and Zn association. **Conclusions:** These outcomes suggest that the supplementation with Zn of DAPA treatment, enhanced the DAPA effect on decreasing the glycemia, restored the liver function, improved the lipid metabolism, and reduced the oxidative stress in STZ-induced DM in rats. **Keywords:** ZINC, STREPTOZOTOCIN, DIABETES, RATS, ANTIOXIDANT.

Type 2 DM is a chronic and widespread disease that arises from a combination of genetics and environmental factors, including sedentary lifestyle and obesity. The disease and its complications pose a significant public health challenge globally affecting both developed and developing countries with high rates of morbidity and mortality.

Unfortunately, the prevalence of type 2 DM is rapidly increasing, particularly in populations undergoing modernization. The disease often remains undiagnosed until serious complications emerge, and many risk factors are associated with it. The existing therapies are often ineffective and expensive, highlighting the need for new, efficient prevention and treatment strategies.

The selective glucose-sodium cotransporter 2 (SGLT2) inhibitors (empagliflozin, dapa-gliflozin, canagliflozin) belong to a new class of drugs approved for use as antihyperglycemic therapy (1). They reduce plasma concentrations of glucose through the renal inhibition of its reabsorption, inducing glucosuria (2). Their actions include: the decreasing glycated hemoglobin, the lowering postprandial blood glucose, reducing body weight and blood pressure (3-5).

In healthy individuals, 90% of the filtered glucose is reabsorbed by the glucose-sodium cotransporter 2 (SGLT-2) in the renal proximal convoluted tubule, and the remaining 10% is reabsorbed by the SGLT-1 transporter with a high affinity, in the right segment of the proximal descending tube (6, 7). In nondiabetic subjects, no glucose appears in the urine until the plasma glucose concentration exceeds 180-200 mg/dl, at which point all excess filtered glucose is eliminated. In people with DM, the threshold at which glucose appears in the urine, as well as the maximal renal tubular reabsorption capacity, are significantly increased, thus contributing to the maintenance of hyperglycemia (8, 9).

SGLT2 is expressed in the proximal tubule and mediates the reabsorption of approximately 90% of the filtered glucose. SGLT2 inhibitors promote renal glucose excretion and therefore modestly reduce high blood glucose levels in patients with type 2 diabetes (10). The ability to lower blood glucose and glycated hemoglobin levels is limited by the amount of filtered glucose and the osmotic diuresis caused by this medication. Although the SGLT2 inhibitors currently on the mark*et al*most completely block tubular glucose reabsorption, the measured inhibition is less than 50%, estimated based on urinary glucose excretion (11,12).

Zinc is a trace element with an essential role for growth, immunity, has antioxidant properties, and participates in the storage and processing of insulin in the body (13). Data from the literature show that the administration of zinc supplements in patients with type 2 DM improves the symptoms of the disease, as a result of the decrease in the level of cholesterol and glycated hemoglobin in the blood (14-16). Normally, zinc is concentrated in the pancreatic beta cells, at the level of the dense nucleus of the insulin-secreting granules, being essential for the formation of insulin crystals, its release, transport, storage and processing in the body (17,18).

The **purpose** of our study was the experimental research on the effects of DAPA and its association with Zn in rats with experimental-induced DM.

MATERIAL AND METHOD

Substances

STZ (molecular weight of 265.221 g/mol, catalogue code: S0130), buffer citrate (0.1 M, pH 4.5, catalogue code: P4809), DAPA (≥ 98% HPLC, molecular weight of 408.87 g/mol, catalogue code: SML2804) and Zn (molecular weight of 136.30 g/mol, catalogue code: 429430) were procured from Sigma-Aldrich, Chemical Co (Steinheim, Germany).

Animals

Healthy, non-genetically engineered white Wistar rats, weight between 150 and 200 g weight) were purchased from the National Medical-Military Institute for Research and Development, Băneasa, Bucharest, Romania through the Biobase of "Grigore T. Popa" University and Medicine and Pharmacy from Iasi and CEMEX (Advanced Research and Development Center for Experimental Medicine), Iasi, Romania.

The rats were housed in individually plexiglass cages and acclimatized for 7 days, in constant laboratory environment with a controlled temperature of 21±2°C, a relative humidity of 50-70% and 12-hours light/12-hours darkness alternative cycle. Standard granulated food and tap water were *ad libitum* offered, the daily intake was measured and the animal`s behavior was carefully monitored. All animals were weighted after one and four weeks in the experiment.

The protocol of the experiment

Rats were randomly assigned into five groups (5 animal per group), as follows: Control: citrate buffer; STZ and fat diet; STZ+Zn and fat diet; STZ+DAPA and fat diet; STZ+DAPA+Zn and fat diet. DM was induced in rats, by intraperitoneal administration of a single daily dose of STZ of 20 mg/ kg body weight (kbw), for three consecutive days, and fat diet (10 g cholesterol/100 g diet) for four weeks. After dissolving in citrate buffer (25 µg), STZ was immediately injected. Citrate buffer (0.1 mL/100 g body) was intraperitoneal administered to the control rats. DAPA 1 mg/kbw and Zn 5 mg/kbw were administered orally as a single daily dose, for four weeks.

Few drops of blood collected from caudal vein were used to measure glycemia in twelve hours fasting rats, using an Accu-Chek Go digital glucometer (Roche, Warsaw, Poland). The animals with levels higher than 200 mg/dL were recognized as having diabetes and included in the investigation.

Laboratory investigations

Before inducing diabetes (moment zero - baseline), a week and four weeks after, 0.3 mL blood were collected for biochemical analysis to assess the: ALT (alanine-aminotransferase), AST (aspartate-aminotransferase), cholesterol, HDL (high density lipoprotein), triglycerides using the VITROS 750 XRC Analyzer (Alphasoft, Bochum, Germany) with specific Johnson & Johnson (Johnson, New Haven, USA) reactors.

The influence of substance tested on the oxidative processes was investigated by evaluation of SOD (superoxide dismutase) and MDA (malondialdehyde) activity. The estimation of SOD activity was carried out by spectrophotometric analysis, using specific kits from the RANSOD kit (catalogue code19160-1KT-F) of RANDOX Laboratories Ltd. (Crumlin, UK). The analysis of SOD activity is based on the inhibition of the reduction of nitroblue tetrazolium, with xanthine-xanthine oxidase, used as a superoxide generator (19). The measurement of MDA blood values was performed by chromatography, using the thiobarbituric acid test as a marker of lipid peroxidation and free radical generation (20). For the HPLC (high performance liquid chromatography) method, a particular kit (catalogue code ABIN772058) bought from Redox, Bucharest, Romania was used.

Ethical aspects of the research

The research methodology was approved by our University Committee for Research and Ethical Issues (Certificate No. 30/14.01.2021) and was carried out in accordance with international standards (21)

about the handling of laboratory animals.

Statistical analysis

The mean ± standard deviation (S.D.) of average values was calculated for each group and the statistical differences among the groups were assessed using SPSS software version 17.0 for Windows and EXCEL application (IBM, New York, United States). The probability (*p*) values below 0.05 were estimated to be significant versus control group.

RESULTS

At the beginning of the experiment, no significant variations in the animals body weight between STZ, STX+Zn, STZ+DAPA, STZ+DAPA+Zn groups, and the group treated with buffer citrate were observed (fig. 1). The administration of STZ and cholesterol was associated with a continuous increase in the rats' body weight over time, which became statistically relevant versus control group (*p<0.05), but also compared to the beginning of the experiment (♦p<0.05), after one month (fig. 1). The use of Zn, DAPA and DAPA+Zn in rats with STZ and fat diet, lowered the body weight; but no significant differences were revealed between groups, as well as compared to buffer citrate group, and to baseline, at both moments of the evaluation (fig. 1).

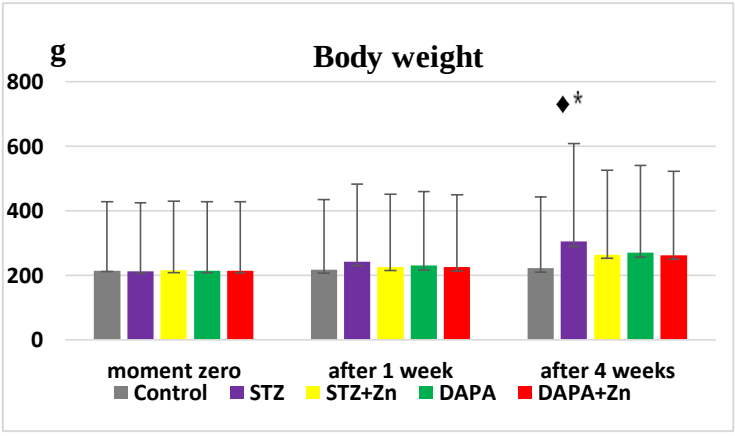

Fig. 1. The influence of DAPA, Zn and their association on the body weight in rats with STZ-induced diabetes. *p<0.05 compared to control; ♦p<0.05 compared to moment zero.

Before the inducing of DM, no modifications in glycemia values between the groups studied were observed (fig. 2). The rats with DM after the administration of STZ injection and fat diet, exhibited a progressive increase in serum sugar levels, with a statistical relevance significant compared to control group, after 7 days (**p<0.01), respectively after 4 weeks (**p<0.01). At both moments of the observation the blood glucose values were considerably higher (♦♦p<0.01) versus baseline (fig. 2).

In the diabetic rats the treatment with Zn, DAPA, or their association, prevent the increase in glycemia, which were still slightly elevated, but without relevance compared to buffer citrate group, after one week. Thereafter, the blood glucose levels were progressive diminished becoming insignificant compared to the control group after one month in the experiment (fig. 2).

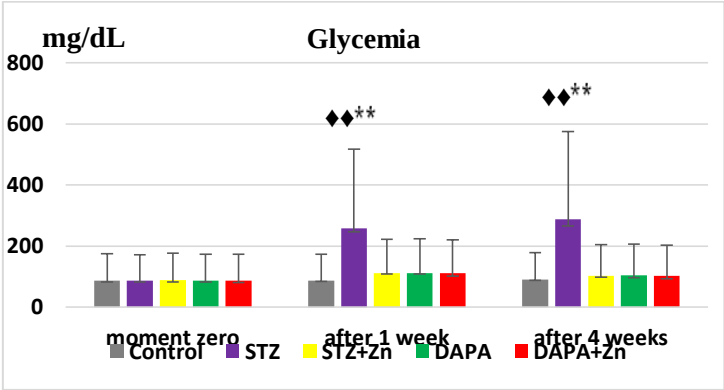

Fig. 2. The effects of DAPA, Zn and their association on the blood glucose levels in rats with STZ-induced diabetes. **p<0.01 compared to control; ♦♦p<0.01 compared to moment zero.

The induced DM with STZ on rats was accompanied by an increase of ALT and AST activity which became relevant after one month, compared to citrate buffer group (*p<0.05), as well as to the moment zero (♦p<0.05) in the experiment (tab. I). The use of Zn, DAPA, respectively DAPA+Zn in animals with STZ-induced diabetes resulted in a considerable decrease in the blood values of these two liver enzymes, their levels being comparable with those of control group at both moments of the investigation (tab. I).

The effects of the substances tested on the decreasing of ALT respectively of AST activity after 7 days, were in the descending comparison as following: STZ+DAPA+Zn > STZ+Zn > STZ+DAPA. Similar ranking was revealed for the blood levels of the transaminases after 4 weeks in the experiment (tab. I).

There were evidenced no important dissimilarities in the blood values of total cholesterol, HDL and triglycerides in the groups studied at moment zero (tab. II). In the STZ group a significant increase in serum total cholesterol levels, after one week, as well after four weeks of monitoring, statistically significant compared to control group (*p<0.05), respectively to the moment zero (♦p<0.05) (tab. II). At the same time an important increasing in triglyceride and a reduction in HDL values were noted after one month in the experiment, statistically relevant versus buffer citrate group, as well as versus the baseline (tab. II).

The treatment with Zn, DAPA and DAPA+Zn was accompanied by a diminution of the cholesterol and triglycerides and increasing of the HDL blood values during the experiment. At both moments of the determination, the intensity of the effects produced by the substances investigated on these parameters of the lipid metabolism, were in descending ordering as following: STZ+ DAPA+Zn > STZ+Zn > STZ+DAPA (tab. II).

No evident variations in the SOD and MDA blood values were shown between STZ, STZ+Zn, STZ+DAPA, STZ+DAPA+Zn and buffer citrate group at the beginning of the experiment (tab. III). In rats with STZ-induced diabetes, was revealed a continuous reduction of SOD, and increase of MD activity, with a statistical significance after four weeks, compared to the control group (*p<0.05), respectively to baseline (♦p<0.05) (tab. III). The treatment with Zn, DAPA and DAPA+Zn alleviated the disturbances of these two enzymes activity

during the interval of monitoring. At both time moments of the evaluation their serum levels were similar to control group, respectively to baseline (tab. III).

The effects on the specific markers of oxidative reactions varied in intensity following the exposure to the studied substances, and were observed both at one and four weeks, being in descending classification as following: STZ+DAPA+Zn > STZ+Zn > STZ+DAPA (tab. III).

DISCUSSION

Literature data revealed that SGLT2 inhibitors readily reduce blood pressure and body weight, particularly due to their glycosuric effect. Currently, empagliflozin and canagliflozin have also been shown to improve cardiovascular status in high-risk patients and slow the progression of kidney disease in diabetics (22, 23). Regarding their clinical efficacy, it is important to emphasize the obvious metabolic benefit of SGLT2 inhibitors, when used in place of other antihyperglycemic agents, such as sulfonylureas, or to reduce the daily dose of insulin (24, 25). Very important are their osmotic diuretic and natriuretic effects, which contribute to the reduction of plasma volume and the decrease of systolic and diastolic arterial pressure, which explains the cardiovascular and renal benefits (11, 26). SGLT2 inhibition is also associated with a rapid, dose-dependent decrease in glomerular filtration rate and reduction in albuminuria (27, 28).

It is known that in patients with diabetes, the zinc content of the pancreas is very low, the serum zinc levels are low, as a result of its loss due to excessive urination. Low levels of zinc in the blood plasma prevent the islets of Langerhans from secreting and producing insulin (29). Also, this divalent cation plays an important role in the antioxidant defense in patients with type 2 diabetes, in particular by acting as a cofactor of

superoxide dismutase, by modulating glutathione metabolism and metallothionein expression, by competing with iron and copper, at the cell membrane level and by inhibiting nicotinamide adenine dinucleotide phosphate oxidase. Zinc alleviates oxidative stress in these patients, by reducing chronic hyperglycemia, with the promotion of insulin receptor phosphorylation, as a result of increased glucose transport in cells (30).

Recent outcome trail data indicate that DAPA not only improves hyperglycemia but also slows the progression of DM-associated glomerulosclerosis and liver fibrosis by improving hyperglycemia-induced tissue inflammation and oxidative stress by reducing levels of ROS, MDA and increased antioxidant enzymes, including SOD and glutathione peroxidase (31,32). Other studies highlight that diabetic rat subjected to treatment with Zn experienced weight loss and a reduction in blood sugar levels. The addition of Zn to their diet resulted in a significant decrease in oxidative stress, preserved the pancreatic architecture, and restored both liver and kidney function and structure in rats with STZ-induced diabetes (33, 34).

In our research we evidenced an increase in body weight occurred in all groups in the study throughout the duration of the experiment, both the one measured at seven days and the one measured at four weeks. It was found that in the control group, the weight increase was the lowest, the highest increase being registered in the STZ and fat diet group. Although an increase in body weight versus baseline was noticed in all the other groups, this was the lowest in the STZ+Dapa+Zn group, probably due to the synergistic action of DAPA and Zn. Similar observation could be done about the modification in blood glucose values.

In rats with STZ and fat diet-induced DM, an increase in ALT and AST enzymes activity, in total cholesterol and triglyceride levels and a decrease in HLD-cholesterol blood values were observed in all study groups compared to the control group and baseline. Also, the weight gain caused by the administration of STZ, and high-fat diet was recorded in all study groups, but the most significant decrease was observed in the group treated with DAPA+Zn, probably due to the synergistic action of the two substances.

The treatment with Zn, DAPA and their combination resulted in a significant decrease in blood sugar levels in diabetic rats, in all groups studied. The administration of Zn, DAPA, respectively DAPA+Zn in animals with STZ-induced DM led to a significant improvement in the blood values of liver enzymes ALT and AST, total cholesterol, triglycerides and HDL-cholesterol, most substantially in the DAPA+Zn group.

CONCLUSIONS

In our experimental conditions, we demonstrated that supplementation with Zn of DAPA treatment enhances the DAPA effect, reduced oxidative stress, restored the liver function and improve lipids levels in STZ-induced DM in rats.

IS THE MANNHEIM INDEX STILL USEFUL IN THE PROGNOSIS OF PATIENTS WITH SECONDARY ACUTE PERITONITIS? (Abstract): Digestive tract perforations or anastomotic dehiscence are the main causes of secondary acute peritonitis, in 80% of cases rapid surgical intervention combined with antibiotic therapy leads to a favorable prognosis. The Mannheim index represents a simple and inexpensive score used in acute peritonitis, which was originally derived from a study on 1253 patients with peritonitis treated between 1963 and 1979. **Material and methods:** We performed a retrospective study on 185 patients, hospitalized with the diagnosis of acute peritonitis who underwent surgery, in the general surgery clinic of the Emergency Clinical Hospital "Bagdasar-Arseni" Bucharest between 2016 and 2019. The patients were grouped into 4 risk groups according to the Mannheim index as follows: < 12, 12 - 20, 21 - 27, > 27. **Results:** A value of the Mannheim index below 12 was recorded in 75 patients with a mortality of 8%, values between 12 and 20 were in 59 patients with a mortality of 13.55%, values between 21 and 27 were in 40 patients with a mortality of 25% and a Mannheim index value above 27 were in 11 patients with a mortality of 63.63%. **Conclusions:** The Mannheim Index may be a useful predictor of progression, and further analysis may be beneficial to explore this relationship further. **Keywords:** PERITONITIS, DIGESTIVE PERFORATION, PEPTIC ULCER, MANNHEIM INDEX.

Digestive tract perforations or anastomotic dehiscence are the main causes of secondary acute peritonitis, in 80% of cases rapid surgery combined with antibiotic therapy leads to a favorable prognosis (1), however, mortality remains high ranging between 17 and 63% (1-6). Severe forms of peritonitis are accompanied by a systemic inflammatory response whose intensity is difficult to anticipate, so we can use the Mannheim index, which represents a simple and cheap prognostic method (7, 8).

The Mannheim index represents a simple and inexpensive score used in acute

peritonitis, which was originally derived from a study of 1253 patients with peritonitis treated between 1963 and 1979 (7). It was composed by analyzing 17 risk factors among which 8 represented prognostic factors, being widely used in the prediction of mortality from acute peritonitis (9).

MATERIAL AND METHODS

We performed a retrospective study on 185 patients, hospitalized with a diagnosis of acute peritonitis and operated on, in the general surgery clinic of the Emergency Clinical Hospital "Bagdasar-Arseni" Bucharest between 2016 and 2019. The patients were grouped into 3 groups of risk, < 21, between 22 and 29 respectively > 30, and then in 4 risk groups according to the Mannheim index (Table 1) as follows: < 12, 12 - 20, 21 - 27, > 27.

The data obtained from the analysis of the variables recorded from the patients were subjected to statistical analysis through *Microsoft Excel* and *SPSS* applications, using Crosstabulation, Chi-Square, and Symmetric Measures tests.

TABLE I.

Mannheim peritonitis index

Mannheim peritonitis index	
Risk Factor	Score
Age > 50 years	5
Female sex	5
Organ failure	7
Malignancy	4
Origin of sepsis not colonic	4
Diffuse generalized peritonitis	6
Preoperative duration of peritonitis	4
Intraperitoneal exudates	
Clear	0
Cloudy, purulent	6
Fecal	12
Organ failure	
Kidney	
Creatinine level	≥ 177 μmol/L (≥ 2,31 mg/dL)
Urea level	≥ 167 mmol/l (≥467,78 mg/dL)
Oliguria	<20 ml/h
Lung (mmHg)	
PaO_2	< 50
$PaCO_2$	> 50
Shock	Hypodynamic or hyperdynamic
Intestinal obstruction (only if profound)	With paralytic ileus > 24 h, complete mechanical

RESULTS

Of the 185 patients included in the study, we had a total of 115 male patients (62.2%) and 70 female patients (37.8%), aged between 9 and 86 years, with a value average of 51.46 years and a median of 49 years, 48.64% aged over 50 years, most of the patients in the studied group, 60.54%,

coming from the urban environment.

A percentage of 92.43% of patients presented as an emergency, and the most common causes of peritonitis were represented by acute appendicitis with a percentage of 27.6% and perforated ulcer with a percentage of 24.9%, only 16.76% of the causes of peritonitis being of a malignant nature. The onset of symptoms was in most patients more than 72 hours before presentation to the emergency room, the most important symptoms being abdominal pain, nausea, and vomiting. We also mention the fact that at the presentation a percentage of 56.8% of the patients presented a good general condition, 25.4% presented an alteration of the general condition, and 15.7% of the patients at the time of presentation had established toxic-septic shock.

At the time of presentation, organ failure was found in 18 patients, in most cases, 10, being multiple organ failure.

Regarding the intraoperative appearance, in 55.68% of cases, the peritonitis was generalized, the appearance of the intraperitoneal fluid in 52.4% of cases was clear, in 37.3% purulent, in 6.5% fecaloid and 3.8% bilious.

Out of a total of 185 patients, 154 (83.2%) showed a favorable evolution, while 31 died, thus registering a mortality of 16.75%.

The values of the Mannheim index were between 0 and 43 with an average of 15.43 and a median of 15. We decided to group the patients into 3 risk groups, < 21, between 22 and 29 respectively > 30 according to the Mannheim index, in the group with values below 21 were 149 patients of which 13 died, revealing mortality of 8.72%, in the group with values between 22 and 29 we had 27 patients of which 10 died, revealing mortality of 58, 82%, and in the group with values over 29 we had 9 patients, 6 of whom died, revealing mortality of 66.66%. (tab. II). The data were analyzed statistically; thus, Chi-Square tests were performed obtaining a p-value between 0.000000554 and 0.000000087 and Symmetric Measures with a p-value between 0.000000554 and 0.000242805.

TABLE II.

Distribution of patients by Mannheim Index and mortality

		Favorable	Death	Total	Mortality (%)
Mannheim Index	< 21	134	13	149	8.72
	22 - 29	17	10	27	58.82
	>29	3 2	6	9	66.66
Total		154	31	185	16.75

Since the mortality in the group with values between 22 and 29 and in the group with values above 29 was approximately close, we decided to group the patients into 4 categories according to the Mannheim index as follows, < 12, between 12 and 20, between 21 and 27 and >27. Thus, in the group with a value below 12, only 75 patients were registered, out of which 6 died, revealing a mortality rate of 8%, in the group with values between 12 and 20, there were 59 patients, of which 8 died, revealing a mortality rate of 13.55%, in the group with values between 21 and 27 there were 40 patients of which 10 died revealing a mortality rate of 25% and in the group with Mannheim index value over 27 there were 11 patients of which 7 died revealing a

mortality rate of 63.63%. (tab. III) The data were analyzed statistically; thus, Chi-Square tests were performed obtaining a p-value between 0.00001824 and 0.00024998 and Symmetric Measures with a p-value between 0.00001183 and 0.00008787.

TABLE III.
Distribution of patients by Mannheim Index and mortality

		Favorable	Death	Total	Mortality (%)
Mannheim Index	<12	69	6	75	8.00
	12 - 20	51	8	59	13.55
	21 - 27	30	10	40	25.00
	>27	4	7	11	63.63
Total		154	31	185	16.75

DISCUSSION

Mortality in acute peritonitis is between 6 and 40% (2, 10-15), an important risk factor being organ failure (16) in our study, mortality was 16.75%.

In our study, 62.16% of patients were male, compared to other studies in which 70.6% of patients were male (10) but also different from other studies in which the percentage of male patients was between 43 and 52% (11, 13). At the same time, the studies do not record gender as a risk factor in acute peritonitis (10, 11, 13).

In many studies, Mannheim index values are divided into 3 groups: under 21, associated with low mortality, between 21 and 29 and over 29, associated with a mortality rate of up to 100% (12, 17, 18), many authors consider that a Mannheim index greater than 26 is associated with high morbidity and mortality (2, 5, 8, 10, 11, 17, 19-21).

In our study, in the case of Mannheim index values below 21, we had a mortality of 8.72%, the group with a value between 22 and 29 had a mortality of 58.82%, and patients with values above 29 had a mortality of 66.66%. For better statistical relevance in our study, we divided the patients into 4 categories according to the Mannheim index as follows, < 12 associated with a mortality of 8%, between 12 and 20 associated with a mortality of 13.55%, between 21 and 27 associated with a mortality of 25% and >27 associated with a mortality of 63.63%. This fact indicates that this prediction cannot be applied individually in terms of making therapeutic decisions in a single individual, a fact also confirmed by multicenter studies performed on large groups of patients (2, 10).

Contrary to the statements previously mentioned, certain studies support the fact that the Mannheim index can be used as a criterion in choosing the optimal treatment of acute peritonitis (17, 18 ,20), laparoscopic treatment is indicated for a Mannheim index with a value below 29 (10, 17, 22, 23).

The Mannheim index represents a severity score that is easy to use in the clinic, studies that compared it with the APACHE II score, peritonitis index of Altona, and sepsis severity score demonstrated its value, being equal or superior in assessing the prognosis (5, 12, 18, 24, 25).

CONCLUSIONS

The Mannheim index is a useful score in predicting mortality in acute peritonitis.

Based on the results obtained in our study we can conclude that there is a significant association between the Mannheim index and the evolution of patients. The Mannheim index may be a useful predictor of progression, and further analysis may be beneficial to explore this relationship further.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

TYPES OF DYSPLASTIC LESIONS AND COMPLIANCE WITH FOLLOW UP IN NORTHEASTERN ROMANIA - A RETROSPECTIVE STUDY (Abstract): Cervical cancer is a worrisome condition as it correlates with a high mortality rate although being one of the most preventable cancer types. **Material and methods**: The medical data of all patients subjected to an excisional procedure between 2000 and 2020 were retrospectively analyzed. Thus, data regarding age, obstetric history, types of dysplastic lesions in the history, HPV infection status, colposcopic findings, identified dysplastic lesions, and the number of screening tests performed were analyzed. Data entry and analysis were performed using SPSS software version 20. **Results:** The study included 455 patients aged between 19 and 62 years old, mean age of 36 years and a standard deviation of 9.07. The analysis of the initial cytology results revealed that the most frequently identified dysplastic lesion was HSIL (High Grade Squamous Intraepithelial Lesion), closely followed by LSIL (Low-grade squamous intraepithelial lesion). The analysis of HPV DNA test recommendations highlighted the fact that in over 50% of cases this test was not performed. In the cases in which DNA HPV test was performed, strains 16 and 18 were most frequently identified. The colposcopic examination revealed that the lesions located within the transformation zone were the most numerous. Of the described lesions, the acetowhite epithelium was most often identified, either isolated or in combination with punctation, mosaic pattern of vascularization or leukoplakia. Conization and LLETZ (Large Loop Excision of the Transformation Zone) were the two excisional procedures used in 46.4% and 44% of the patients, respectively. Histopathological examination showed: 12.5% of the patients presented high-grade HSIL (CIN3) lesions, 47.5% low-grade CIN 1 lesions, and 7% were diagnosed with carcinoma in situ. In the post-intervention follow-up, a total of 202 patients (44.39%) showed up for the first and only 66 patients (14.5%) returned for the second post-intervention follow-up. **Conclusions**: The types of dysplastic lesions identified by cytology were found to be in percentages similar to those reported in the literature, with the exception of HSIL diagnosis, which was the most frequently identified. This high rate could explain the increased incidence of cervical cancer in our country. Conization and excision procedures represent a valuable method of conservative treatment, preserving at the same time patient's fertility and avoiding a radical intervention. Low compliance with follow-up among patients from the northeastern region of Romania and the increasing migration of the groups at high risk made us use these excisional procedures even in the case of low-grade lesions in an attempt to reduce the incidence of this disease. **Keywords:** CERVICAL DYSPLASIA, MONITORING, LLETZ, CERVICAL CANCER.

Globally, cervical cancer is the most commonly diagnosed cancer in 23 countries. In recent decades, incidence and mortality rates have decreased in most areas of the world. These declines are attributed to factors related either to the increase in the average socioeconomic status of the target population, or to a lower risk of persistent infection with high-risk HPV resulting from improved genital and sexual hygiene, low parity, and a decreasing prevalence of sexually transmitted diseases. Cervical cancer screening programs have greatly improved the prognosis of this disease after their implementation in many countries in Europe, Oceania and North America. In the absence of effective screening, as is the case in Eastern Europe and Central Asia, rapid increases in premature mortality from cervical cancer have been recorded in recent years (1). Cervical cancer is a worrisome condition because it correlates with a high mortality rate, although being one of the most preventable types of cancer (2). Regarding the measures that can be taken in order to decrease the prevalence, incidence, and mortality of cervical cancer, an optimal system of actions should include the long-term follow-up of both the processes and the results of the three basic activities: vaccination, screening and treatment - as outlined in the global strategy of the World Health Organization (WHO) to eliminate cervical cancer as a public health problem. However, these measures have not been implemented fairly and directly in all countries. As of May 2020, less than 30% of low-income countries have implemented national HPV vaccination programs, compared to over 80% in high-income countries (1). Unfortunately, the importance of early diagnosis and prevention of cervical cancer is still underestimated by the general population of Romania; however, as shown by the analyzed data, in the past 10 years young patients (aged 25-40 years) have demonstrated an increased interest in routine gynecological check-ups. So, in this context, we conducted a retrospective study that evaluates the types of cervical lesions detected in northeastern Romania over a 20-year period, compliance with follow-up, as well as the risk of cervical dysplasia recurrence among patients who underwent an excisional procedure.

MATERIAL AND METHODS

To achieve this goal, we retrospectively analyzed (using the electronic archive and specific registers) the medical data of all patients subjected to an excisional procedure for dysplastic lesions of various degrees in the interval 2000-2020. The diagnosis and excisional procedure were carried out in a private clinic in Iasi town, being performed by gynecologists with over 10 years of experience in the field. All included patients gave consent for the use of personal information for health research and subsequent inclusion in the study. The data on appointments, consultations, results, and interventions in a population of 500 patients from the northeastern region of Romania, namely Suceava, Botosani, Iasi, Neamt, Vaslui, and Bacau counties, who presented themselves at the clinic between 2000-2020 were processed. Following the evaluation and application of the inclusion and exclusion criteria, a number of 45 patients were excluded from the study. Thus, data from 455 patients were analyzed, information related to age, obstetric antecedents, types of dysplastic lesions in antecedents, HPV infection status, colposcopic aspects, identified dysplas-

tic lesions, and the number of follow-ups. The inclusion criteria were presence of cervical dysplasia or HPV infection, age 18-65 years, sexually active, non-pregnant, intact uterus, without previous treatment for cervical intraepithelial neoplasia. The exclusion criteria were withdrawal of consent, invasive genital cancer at diagnosis, pregnancy, previous cervical excisional procedures, acute bacterial or mycotic cervical-vaginitis, chronic diseases such as liver cirrhosis, kidney failure, cardiovascular diseases, drug addiction or psychiatric diseases. The main goal of the study was to evaluate the types of dysplastic lesions in the northeastern region of Romania, as well as patients' compliance with follow-up in order to identify a possible cause that could explain the increased incidence of cervical cancer among the population in this geographical region. Data entry and analysis were performed using software *SPSS version 20* using descriptive and inferential statistics. In order to maintain data confidentiality and protect the identity of the patients included in the study, the personal data were anonymized. The presented cytological findings are from cervicovaginal smears collected with a specific cervical brush with the help of which cells were taken from the level of the endo and exocolus and prepared mainly in ThinPrep liquid medium (70% of cases), but also from conventional smears, the staining method being the classic one, Papanicolaou. For reporting the results of cervical cytology, the 2014 Bethesda System was used. HPV detection and genotyping were performed by isolation from the collected cervical samples on ThinPrep medium by the gynecologist, later a polymerase chain reaction (PCR) with colorimetric detection and hybridization being used. All samples were processed in RENAR accredited laboratories. Colposcopic and histological examinations were performed if a diagnosis of atypical squamous cells of undetermined significance (ASCUS) or high-grade atypical squamous cells (ASC-H), low-grade intraepithelial lesion (LSIL), high-grade intraepithelial lesion (HSIL) or carcinoma in situ was made. The colposcopic examination was performed with Video colposcope Full HD DCS 102 PRO by doctors certified in colposcopy and with more than 10 years of experience. During the colposcopic examination performed in the patients included in the study 3 parameters were considered to determine the need for biopsy. Criterion I: colposcopic impression of lesion severity or lesion grade (G) with three degrees of severity: G1: colposcopic appearance of low-grade lesion, G2: colposcopic appearance of high-grade lesion, but without signs that could suggest invasion, G3 : colposcopic appearance of invasive lesion with signs of severity: atypical vessels, ulcerations, congestion, erosions, vegetative lesions; Criterion 2: the position of the inner line of the transformation zone (TZ) or the squamocolumnar junction line (SCJ): Type 1 (TZ1): The SCJ is fully visible and is located fully on the ectocervix; Type 2 (TZ2): The SCJ is fully visible and is located either fully or partially within the endocervical canal; Type 3 (TZ3): The SCJ is invisible being located within the endocervical canal; Criterion 3: atypical size or area of the transformation zone (Q): Q1: a single quadrant covered by the atypical transformation zone, Q2: two quadrants covered by the atypical transformation zone, Q3-Q4: three or four quadrants covered by the atypical zone transformation (3). Resection techniques included conization, Loop Electrosurgical Excision Proce-

dure (LEEP) or Large Loop Excision of Transformational Zone (LLETZ). The specimens were initially examined macroscopically and later the blocks were paraffin embedded and stained using the classic hematoxylin-eosin (HE) staining method.

This study was conducted in compliance with the principles of the Declaration of Helsinki and approved by the Research Ethics Committee of the Iasi "Grigore T. Popa" University of Medicine and Pharmacy, registration number 57/17.03.2021.

RESULTS

The study included 455 patients who underwent excisional procedures for dysplastic lesions of various degrees. The study group was divided into 5 groups depending on the type of dysplastic lesions, but also based on cytology findings according to the Bethesda classification: ASCUS (20.4%), ASCH (14.9%), LSIL (30.3%) , HSIL (32.3%), CIS (2%) (tab. II). The study patients were aged 19 to 62 years, average age 36 years, standard deviation = 9.07. The highest percentage (38%) of patients presenting to the clinic for the assessment of dysplastic lesions were aged 31-40 years, and the lowest rate of presentation to the doctor, of only 9%, was recorded in patients aged 19-24 years. As to seeking medical advice, a first maximum peak was recorded in patients aged 27 and a second in those aged 34-35, subsequently the number of patients falling below 15% after the age of 44 (fig. 1).

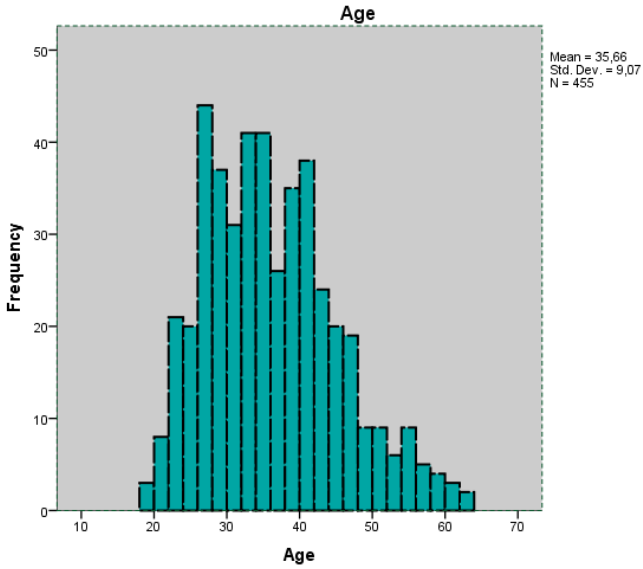

Fig. 1. Age-group frequency

Obstetric history included questions about the number of births and abortions, data that could influence the management of the identified cervical lesions. A maximum of 6 births per patient (with an average of 2 births per patient) with a standard deviation of 1.05, respectively 5 abortions per patient (with an average of 1 abortion per patient) with a standard deviation of 1.07 were recorded (tab. I). The Kruskal

Wallis test was used to compare the abortion and birth rates by maternal age and found that the distribution of abortions does not change with patients' age ($p>0.05$), while obviously the number of births varied by age ($p<0.05$) .

TABLE I.

Obstetrical history of the study patients. Descriptive Statistics

	N	Minimum	Maximum	Mean	Std. Deviation
Number of Births	455	0	6	1.23	1.053
Number of Abortions	455	0	5	0.72	1.079

The analysis of the initial cytodiagnosis revealed that the 455 patients presented the following pathological aspects: the most frequent diagnosis was HSIL, closely followed by LSIL. An initial cytological diagnosis of carcinoma in situ (CIS) was made in 2% of cases. The distribution of these lesions is detailed in table II. Age-distribution according to the type of lesions differed ($p<0.05$), being higher in the case of carcinomas and high-grade lesions and lower in the case of low-grade lesions (fig. 2).

TABLE II.

Distribution of dysplastic lesions

	Frequency	Percent	Valid Percent	Cumulative Percent
ASCH (2)	68	14.9	14.9	14.9
ASCUS (1)	93	20.4	20.4	35.4
CIS (5)	9	2.0	2.00	37.4
HSIL (4)	147	32.3	32.3	69.7
LSIL (3)	138	30.3	30.3	100.0
Total	455	100.0	100.0	

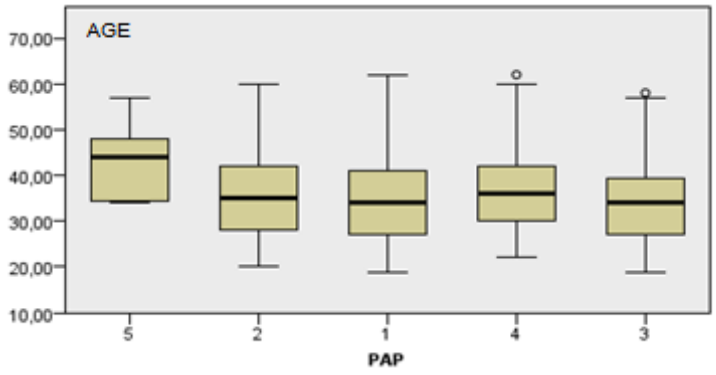

Fig. 2. Age distribution according to the type of dysplastic lesions

The analysis of the data on HPV DNA testing revealed ca over 50% of the study women never had a HPV DNA test, and in the patients in which virus typing was done

the most frequently identified were strains 16 si 18, both as unique strain and in association with other high risk (HR) and low risk (LR) strains.

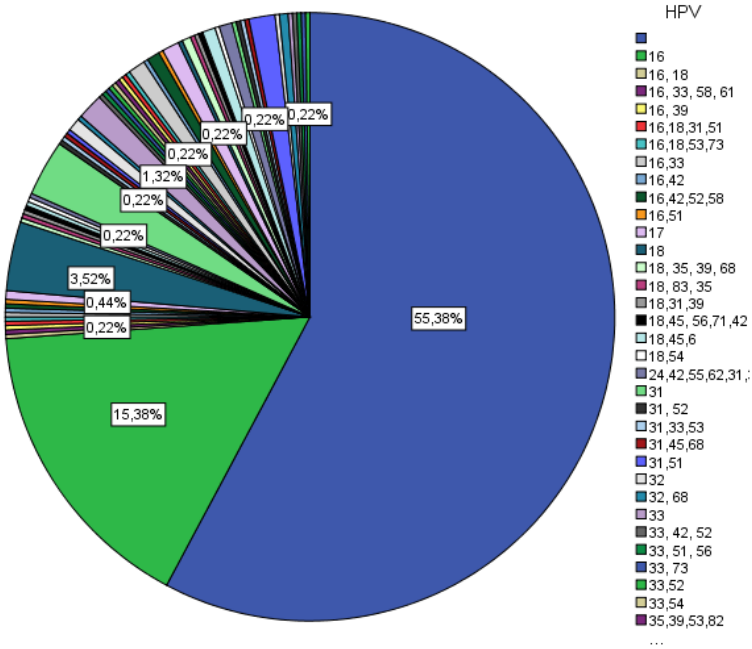

Fig. 3. Distribution of cases according to HPV genotyping results

Distribution of HPV strains in the tested patients revealed that the dominant strain was HPV 16, with most of the test being performed in the 26-30 years age group. The prevalence of HR-HPV and HPV 16 strains was found in women aged 24-41 years, after that the infection rate started to decrease.

All 455 study participants underwent colposcopic examination. Colposcopy results showed that the SCJ was visible in 72.81% of cases (fig. 4). Later, during the colposcopic examination, the 3 parameters used to determine the need for biopsy were analyzed: lesion grade (G), squamocolumnar junction (SCJ) and surface of the atypical transformation zone (Q). The obtained results were: G1/low-grade lesions were identified in over 60% of cases (fig. 4); SCJ was fully visible in 56.4%, partially visible in 30.79%, and could not be identified in 12.81% of cases. The percentage of lesions located solely within the TZ was the highest, thus confirming the potential for missed diagnosis of neoplasias when they develop predominantly at this level.

Of the described lesions, acetowhite epithelium was the most frequently identified, either isolated or in combination with mosaic and punctate vascular patterns or leukoplakia. The mosaic pattern was also seen in 116 examinations and the punctate pattern in 119 examinations. It was found that Mosaic patterns were also seen in 116 examinations and the dotted pattern in 119 examinations. Most colposcopic examinations with pathological findings had lesions limited to 1 or 2 quadrants; in the group with lesions extended to 3 or 4 quadrants, 10 cases with endometrial or vaginal extension were identified.

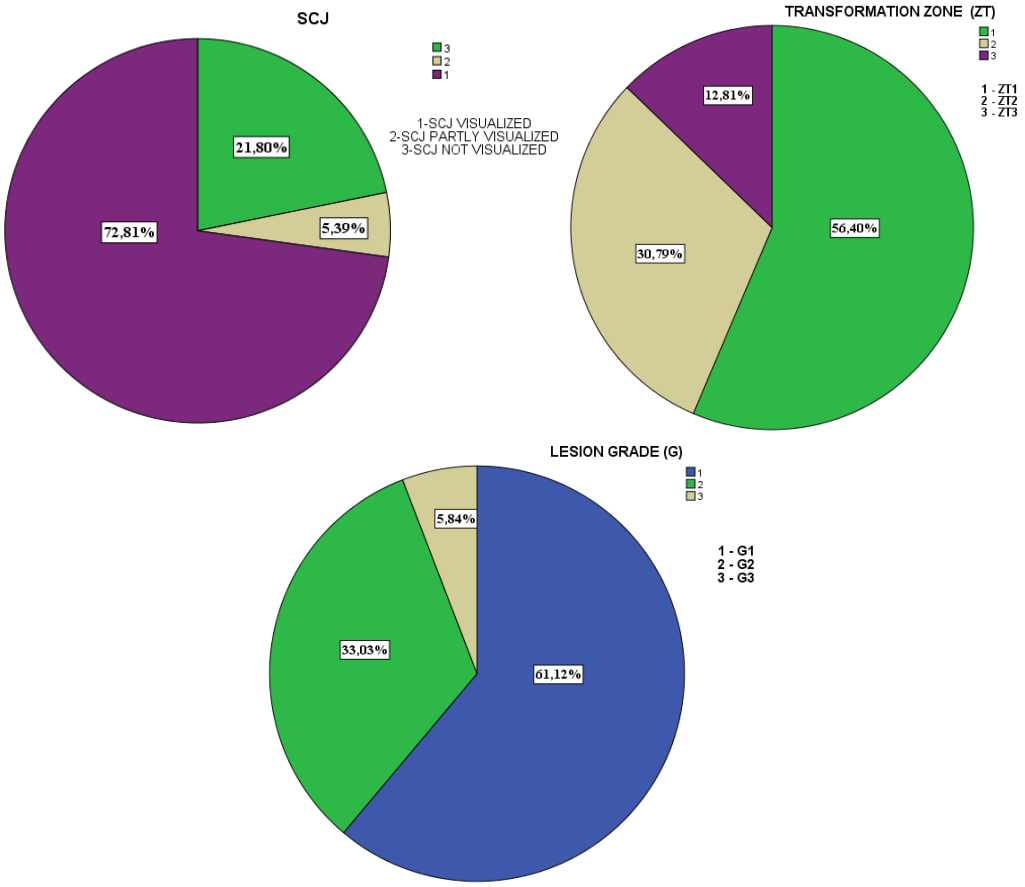

Fig. 4. Squamocolumnar junction (SCJ), Transformation zone, and Lesion grade

Excisional techniques consisted of 2 procedures performed separately or together: conization performed in 46.4% and LLETZ in 44% of the cases, in only 9 cases a colonoscopy with targeted biopsy being performed (tab. III).

TABLE III.
Types of performed excisional procedures

	Frequency	Percentage	Valid Percentage	Cumulative Percentage
	35	7.7	7.7	7.7
BIOPSY	9	2.0	2.0	9.7
CONIZATION	211	46.4	46.4	56.0
LLETZ	200	44.0	44.0	100.0
TOTAL	455	100.0	100.0	

The histopathological findings were: 12.5% of patients had high-grade HSIL (CIN3) lesions (combined or not with lower-grade lesions), 47.5% had a diagnosis of CIN1 (low-grade lesions), and 7% were diagnosed with carcinoma in situ.

Regarding the post-intervention follow-up, a total of 202 patients (44.39%) showed up for the first follow-up. The first follow-up was performed at 1 to 12 months, on average being performed at 3 months with a standard deviation of 2.22. No direct correlation was found between patients' age and post-interventional follow-up, and the low compliance with follow-up did not prove to be related to patients' age, the correlation between the two variables being very weak (R2= 0.01 (fig. 6). However, correlating age with the follow-up rate depending on the performed excisional procedure, most patients showed up for follow-up on average 3 months after the interventional procedure, with LLETZ being the most frequently performed. It is also found that the patients who showed up for the second follow-up were in the age range 26 -45 years old, therefore women of reproductive age. However, a statistically significant correlation between these variables could not be identified (R2=1.18). Thus, we can conclude that the type of performed procedure and compliance to follow-up are not age-dependent (fig. 5).

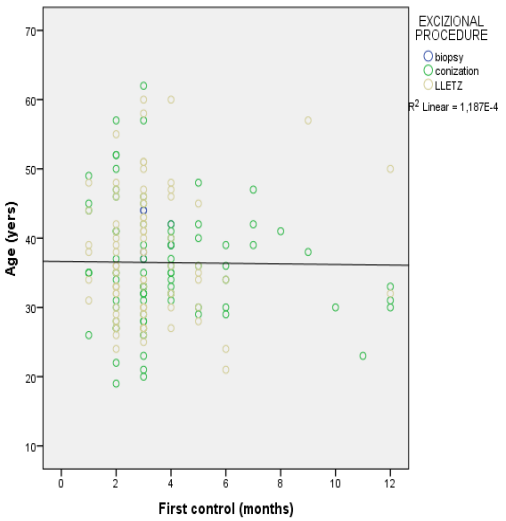

Fig. 5. Correlation between patients' age and compliance with follow-up depending on the excision procedure

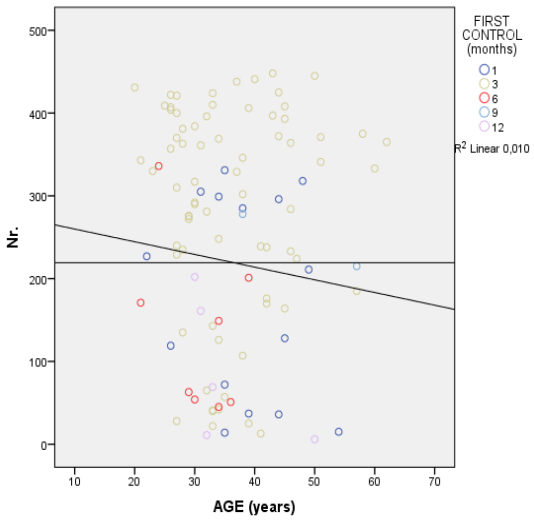

Fig. 6. Correlation between patients' age and time to the first post-interventional follow-up

Of the patients attending the first post-interventional follow-up, only 24 had an HPV test: 12 patients had a positive HPV test result and the remaining 12 negative results, demonstrating a low compliance with performing these investigations. A positive finding is that over 50% of the patients who attended the follow-up had a normal colposcopic appearance of the cervix or had a cytological diagnosis negative for

intraepithelial or malignant lesions; only 6 cases were diagnosed at the cytological re-examination with ASCUS, in 7 cases high-risk lesions were identified (CIN3, HSIL), and in two other patients the colposcopic examination revealed atypical vascularization. As for low-grade lesions, 16 patients who showed up at the first follow-up received a diagnosis of LSIL, CIN1 or CIN2. A single case was diagnosed with CIS 2 months after the first intervention. As for the colposcopies performed in the patients attending the first follow-up, in 15 patients the TZ was visible in different degrees (TZ1, TZ2, TZ3), and on examination the aceto-white epithelium (AWE) had a clear outline in 4 patients or was classified G1 or G2 in 9 patients. In 16 cases a chronic inflammatory process and in other 3 patients an incomplete post-conization scarring were found.

TABLE IV.
Diagnostic findings at the first follow-up

Diagnosis at first follow-up	Number of patients	Percentage
CIS	1	0.49%
HSIL	7	3.46%
LSIL	16	7.92%
ASCUS	6	2.97%
Inflammatory aspects	16	7.92%
NILM	123	60.89%
Colposcopic visualization ZT	15	7.42%
Colposcopic aspect EAA G1/G2	13	6.43%
Colposcopic atypical vascularization	2	0.99%
Other diseases	3	1.48%

Only 66 (14.5%) patients showed up for the second post-interventional follow-up. Cytological examination revealed: 7 patients presented ASCUS features and 4 patients LSIL type lesions, 19 patients had a cytodiagnosis negative for intraepithelial lesions or malignancy (NILM), 14 patients had normal colonoscopic appearance, and 4 patients presented inflammatory aspects (tab. V). Other pathological findings were suggestive of various diagnoses, such as Naboth cysts (1 case), genital mycosis (1 case), TZ ectopy or TZ2 (5 cases), or bacillary flora (1 case). None of the followed-up patients developed CIS or invasive carcinoma. There was only one case with HSIL (followed up at 2- and 4-months post intervention) which at the 7-month follow up was reclassified as LSIL.

Regarding the correlation between age and post-interventional follow-up, no direct correlation was found, low compliance with follow-up being independent of the patients' age. However, the fact that most patients showed up for follow-up 3 months after the interventional procedure, predominantly LLETZ, deserves mention. And so is the fact that the patients who did not miss the follow-up appointments were aged between 26 and 45 years, that is the reproductive years.

TABLE V.
Diagnostic findings at the first follow-up

DIAGNOSIS AT FOLLOW-UP 2	NUMBER OF PATIENTS	PERCENTAGE
ASCUS+LSIL	11	16.6%
Inflammatory aspects	4	6.06%
NILM	19	28.78%
Normal colposcopic findings	14	21.21%
Other diseases	18	27.27%

DISCUSSION

The study population included patients who required an excisional procedure, so the types of dysplastic lesions identified by cytology tests were in different percentages compared to the data in the literature on this topic. Thus, ASCUS-type lesions were identified in 20.4% of our patients compared to 4-5% in the literature. In our study LSIL lesions had an incidence of 30.3%, similar to that of 25-30% reported in the literature on this topic, while for HSIL lesions the incidence in our study was 32.3% versus 8% in the literature. As to carcinomas, the percentages are similar, 2% in our study vs 1% in the literature. These differences can also be explained by the profile of the study population, but at the same time they can raise a question mark regarding the increased incidence of cancer in the northeastern region of our country. The high percentage of severe lesions could be a predictive factor for the high rate of cervical cancer in our country.

Most initial HPV infections are believed to be cleared by the immune system. However, there are people in whom the HPV virus persists in a latent state in cells of the cervix, the latter becoming active through replication mechanisms, leading to dysplasia at a given time in the future. HPV induces pathological changes in the cervix due to the effects of viral proteins expressed by the virus. These changes include basal cell proliferation, nuclear multiplication with hypernucleosis, koilocytosis and abnormal mitoses (4).

The natural history of HPV infection demonstrates that it is often transient in young women, most CIN I and II cases regressing within 2 years of primary infection (5,6). The age range in the population analyzed in our study was 19 - 62 years, average age 36 years, thus most of them socially active young women. We believe that analyzing if patients saw a doctor or general practitioner and the classification of cervical diseases by age group due to future different obstetric implications are an interesting addition. Regarding the first age group in our study, patients under 24 years of age, they accounted for only 9% of all study patients and did not require HPV testing because it is a group at high risk for infection but also for spontaneous remission within 2 years mainly due to individual immunological mechanisms. However, at least those women who are already sexually active should be screened for cervical cancer by cytology.

The age group 25-40 years accounted for 64% of the patients diagnosed with cervical dysplasia included in the study. If to these we add the age group under 24

years we get a total of 73%, meaning that three quarters of the women who require consultations for dysplasia are of childbearing age, the obstetric prognosis being important and essential for this age category. Thus, in addition to preventing cervical cancer, preserving the obstetrical future of these patients has to be another main concern. These observations are in agreement with the data regarding the obstetric history of these patients, the statistical analysis showing that the number of births differs according to age, women aged between 19 and 40 years having more babies than those over 40. So, in women over 40 years, the obstetric prognosis is no longer a priority, the main concern being the prevention of cervical cancer. Also, we found that these women seek medical help less than the younger ones, accounting for only 27% of the examined patients.

The risk of HPV infection in a population increases sharply after the first intercourse. Cohort studies show that after a rapid increase in young women, the incidence of cervical HPV infection decreases with age. On one hand, this decrease is due to fewer sex partners and, on the other hand, to the specific immunity developed by some patients. Of the 203 patients assessed for HPV DNA in our study, 41.38% tested positive for HPV 16, 10.84% tested positive for HPV 18, and 32.02% tested positive for other HPV HR strains than the 2 above mentioned. Thus, the percentage of tests in which high-risk strains were detected exceeded 80%. Comparing the different age groups with positive HPV genotyping an upward trend can be observed, with a peak in high-risk viral DNA detection in patients up to 30 years of age, and a decrease after the age of 40. Fifty-one of the positive cases were up to 30 years old, the result being mainly influenced by the increased rate of infections with high-risk strains at young ages, but also possibly due to an increased level of information of this age group or a particularly favorable socio-economic status. The age-related distribution of HPV is also supported by other studies such as that by Aro *et al.* who evaluated the distribution of HPV types in a cohort of 1,279 women with cervical dysplasia (7) and found that the distribution was distinctly polarized by age. So, in terms of incidence, HPV 16/18 proved to be more common in young women. Another study reported comparable results, HPV16/18-related cervical dysplasia being found in 64%, 58%, and 35% of women aged <30, 30–44, and ≥45, respectively(8). The results are somewhat similar to those obtained in our study.

In our study, excisional interventions were performed in 47.5% of the patients with CIN1 dysplasia, which is low-grade dysplasia, and in 25.3% of the patients with CIN2 dysplasia. This therapeutic approach was based on the following considerations: they were performed when the lesions did not regress spontaneously, in low grade lesions but worrisome for the examiner because they were extended, and also in patients who did not want or did not have the possibility (for various reasons) to comply with the specific follow-up essential to adopt a "wait and see" attitude, as in the case of those from a disadvantaged socio-economic environment. Added to these is the particular group of patients who migrate to other countries for a longer period of time, who do not benefit from medical insurance, and who request a quick solution.

It would have been interesting to study how the patients with cervical anomalies

were followed-up before making the decision to perform excisional interventions, knowing that a high percentage of the dysplastic lesions, especially the low-grade ones, are likely to regress spontaneously. Unfortunately, the vast majority of women included in the study saw a doctor because of a more or less specific symptomatology, rather than for a screening assessment. In these conditions, it is not surprising that the most common therapeutic attitude was conization or LLETZ. It is obvious that from the point of view of specific management, the actions taken, and the approach used in these cases are not in accordance with the international guidelines regarding the management of the cases in which small asymptomatic lesions are discovered.

A discrepancy can be noted between the compliance with follow-up of the patients in the northeastern region of Romania included in the study and that of patients with cervical dysplasia from other countries where a follow-up appointment is scheduled every 6 months in the first 2 years after diagnosis and annually thereafter, and includes pap smear, colposcopy, and colposcopic guided biopsy, of course if clinically indicated. As a rule, HPV testing is performed at the first examination after conization in patients with documented HPV infections. Persistence of HPV infection is defined as HPV identification at the first specific examination after conization (9). In this study, we failed to establish a correlation between the persistence of HPV infection and the degree of cervical lesions, since only 24 patients underwent HPV testing after the excisional procedure.

As to the follow-ups after excisional procedures conducted in the first 3 months after the intervention, it was found that a total of 202 patients showed up for the first post-procedural follow-up, which accounted for over 50% of all examinations. Sixty-six of these patients showed-up for a second follow-up, of which 43 patients in the first 6 months after the intervention. Age-related differences in the low compliance with follow-up were noticed, this aspect not only influencing the visits to a doctor, but also the subsequent follow-up. Although most initial infections in young women are generally eradicated, there are patients in whom the HPV virus persists in the cervical cells in a latent state, the latter becoming active through replication mechanisms leading to dysplasia at a certain time in the future (4). In young women, most CIN 1 and CIN 2 cases regress within 2 years, the treatment and excision being recommended only when CIN2 persists for over 2 years on biopsy according to the guidelines. Regarding the CIN3 lesions, a small percentage will regress, but most of them will progress to cervical cancer. Current recommendations support that CIN3 in young women under 24 years to be managed as is adult women, excisional procedures being recommended (10). Although these new recommendations are medically reasonable, it is important to consider the issue of compliance. Unfortunately, a substantial number of patients is lost to follow-up as shown by our study, where less than half of the patients who underwent excisional procedures showed up for follow-up. Delayed follow-up may result in a delayed initiation of the specific treatment. Data in the literature demonstrate low compliance at 2-year follow-up even after an excisional procedure such as a LEEP (11, 12). Failure to comply with the follow-up protocol was associated with young age, lower education level, unmarried status, inadequate health insurance, better overall health, low grade

cervical lesions, as well as the lack of understanding the severity of their condition (13). Women with a low socioeconomic status and those from minority communities were identified as less likely to accept cervical cytology as a screening method. Furthermore, compliance with follow-up in these cases is much lower after an abnormal result. The absence of monitoring can substantially contribute to an increase in the incidence of invasive cervical carcinoma, this increased incidence already being reported among poor and minority women (14, 15). For all these reasons we believe that delaying additional testing for more than 12 months in patients with abnormal cytology may contribute to a delay in diagnosis and management.

Our study shows that there are no differences regarding patients' compliance with follow-up regardless of disease severity or the performance of an excisional procedure. This lack of compliance with follow-up in the analyzed population may be explained by their low socioeconomic status and increased population exodus. According to the National Institute of Statistics, "Romania continues to be a country of emigration, the phenomenon of emigration being the second main cause of the declining population. The international migration balance of Romania in 2021 was negative" (16). The number of Romanians living abroad is around 5.7 million according to the data of the Ministry of Foreign Affairs, accounting for almost 30% of the country's population (17). This problem explains the sometimes slightly more aggressive therapeutic approach compared to international guidelines. The low compliance with follow-up and the fact that some patients showed up for the first follow-up after the interventional procedure at 6 or 12 months did not allow a relevant correlation of cytodiagnosis in dynamics. Based on the results of the first follow-up after the excisional procedure we can report that 11 patients presented low-grade lesions (ASCUS+LSIL) and HPV HR infection, the group being too small for a statistically significant result. It can be noted that after a longer time interval, over 12 months, no residual high-grade lesions were observed. The literature supports the fact that the persistence of high-risk HPV infection (both HPV16/18 or other HPV HR strains) was correlated with an increased risk of recurrence of CIN 2-3 cervical lesions. Persistence of HPV infection is associated with recurrence, much more than margin status after excisional procedure, being one of the main factors predictable of relapse. This is also supported by Zhang *et al.* (18) who analyzed the data of over 500 patients who underwent conization and observed that positive margins after the excisional cause a 6-fold increase in the risk of recurrence, while the persistence of HPV HR infection cause to a 20-fold increase in the risk of recurrent disease. Considering these results, it is imperative to implement cotesting both for the detection of cervical lesions and for their monitoring (9).

A possible solution could be an organized screening and a much more effective vaccination campaign, which could increase patients' compliance with health services, being able to address this condition before the onset of clinical symptoms and thus minimizing the interventional procedures. In this respect, better ways to inform the population and the mobilization of the target population, the involvement of several health professionals, mobile screening units facilitating access to healthcare services, treatment optimization and fol-

low-up systematization, as well as the establishment of a national registration and tracking register are needed (19). Measures to inform and educate the population about this disease also necessary. Increasing the degree of awareness of this disease severity would increase compliance with follow-up. Primary prevention by vaccination against HPV virus was initiated in 2008 but was eventually abandoned because of parental refusal of vaccines. This opposition is found even in medical circles and even in cancer services. For convincing the parents about the value and safety of vaccination it is still essential that professionals to send a clear message and inspire through the power of example. Secondary prevention through a systematic screening program was initially implemented in 2012 and abandoned subsequently; a new campaign with mobile units was resumed in 2020, the target population being women aged of 25 to 65 years, which is approximately 4.2 million women in Romania. The large sample size is the main strength of the present study, and the most important limitation was the inclusion of a large group of patients who were not tested for HPV. Although being a limitation it reflects the current practice in a "real life" setting. Low compliance with follow-up also reflects a current practice, being a favorable factor for the increased incidence of cervical cancer in our country.

CONCLUSIONS

Although the etiopathogenesis of cervical cancer is strongly associated with HPV infection, not all lesions will undergo malignant transformation as cases of spontaneous remission were demonstrated under adequate monitoring. Cervical cancer is the neoplasia with the most effective preventive methods including vaccination and primary or secondary screening, thus making possible the early detection of precancerous lesions. The types of dysplastic lesions identified by cytological examination are in similar percentages with those reported in the literature, except for the diagnosis of HSIL which is the most frequently identified. This increased rate could be the basis for the increased incidence of cervical cancer in our country. Conization and excisional procedures represent a valuable method of conservative treatment while preserving the patient's fertility and avoiding a radical intervention.

The low compliance with follow-up among the patients in this region of the Romania and the increased population migration are two particular elements that lead to the use of excisional procedures even in the case of low-grade lesions in an attempt to reduce the incidence of cervical cancer. This low compliance to follow-up and the absence of vaccination can justify the fact that Romania ranks first in Europe in terms of the incidence of cervical cancer. The risk of recurrence identified after excisional procedures was low, being correlated with the persistence of HPV infection. Improving the organized screening programs and a more effective vaccination campaign could increase patients' compliance with public health services, being able to deal with this condition before symptoms arise thus minimizing the interventional procedures and progression to cervical cancer.

CONFLICT OF INTEREST AND FUNDING

ANTIBIOTIC TREATMENT AND BACTERIAL FLORA IN SPUTUM IN CHRONIC PULMONARY DISEASE EXACERBATIONS. **Background and aims:** A judicious use of antibiotics for Chronic Obstructive Pulmonary Disease (COPD) or asthma frequent exacerbation is a provocation for clinician. In this context, the aim of our study was to identify and describe the commonest bacterial pathogens and the preferred antibiotic for the treatment of the patients with recurrences for COPD and asthma exacerbations because this category of patients has worse health status and increased morbidity. **Materials and methods:** A retrospective study investigated patients with recurrent COPD or bronchial asthma, more than 2 exacerbations/year and at least one early re-admission, admitted in Iasi University Clinical Hospital of Pulmonary Diseases from North-East Romania, from 2014 to 2019. **Results:** Only 33 patients were selected according to inclusion criteria. A small proportion of sputum culture identified the pathogen (20.35%) and most frequent were *Streptococcus pneumoniae* followed by *Pseudomonas aeruginosa* and *Haemophilus influenzae*. The bacteria identified were resistant to aminopenicillins and 1st - 3rd cephalosporins generation. Quinolones (levofloxacin) and colistin were the preferred antibiogram-based therapy. C**onclusions:** COPD and asthma exacerbation can be a start to antibiotic stewardship because these patients are the most exposed to inappropriate antibiotic use, decompensations, increased hospital stay, increased treatment costs. **Keywords**: ANTIBIOTIC TREATMENT, EXACERBATIONS OF COPD, EXACERBATIONS OF ASTHMA, BACTERIA.

The judicious use of antimicrobial chemotherapy is a priority of global interest, an urgent situation to be also considered in countries where the surveillance programs for their administration did not become yet a priority that requires local and national resources to stop antibiotic resistance.

Chronic respiratory diseases, like asthma and Chronic Obstructive Pulmonary Disease (COPD), are one of the main causes of mortality and morbidity worldwide. In 2017, hospital in-patient admission rates for asthma ranged from 0.12% in Italy to 0.19% in Bulgaria and those for COPD and bronchiectasis ranged from 0.62% in Cy-

prus to 4.70% in Romania (1). Our country it is on second place for hospital discharge rates for in-patients with diseases of the respiratory system, in 2019, after Bulgaria (2). In-patient average length of stay for asthma in our country was 7.8 days in 2014 and 7.9 days in 2019 (3).

Both bacterial and viral infections are predominant causes of COPD exacerbations, but viral infections are predominant causes of asthma exacerbations. Bacterial pathogens in COPD causes approximately half of reported cases. The common bacteria are *Streptococcus pneumoniae*, *Hemophilus influenzae*, *Moraxella catarrhalis*, *Pseudomonas aeruginosa* and *Enterobacteriaceae* and atypical pathogens such as *Chlamydia pneumoniae* (4). According to GOLD recommendations, five to seven days of oral antibiotics should be given to COPD exacerbations that include all three increasing symptoms - sputum purulence, sputum volume and increased dyspnea or evident purulence of sputum. It is recommended to start with an association between amino penicillin and clavulanic acid, tetracyclines (doxycycline) or macrolides (azithromycin), with careful attention to multiple bacterial infections, resistant pathogens, intensive care stay, where identification of the bacteria or cultures are needed (5). According to GINA 2023 recommendations (6), antibiotic treatment is not recommended routinely for asthma exacerbations, unless is evidence of bacterial infections with fever, purulent sputum, radiographic evidence. On the other hand, a recent review of Normansell *et al.*, 2018, showed that the most prescribed antibiotics are macrolides (clarithromycin, azithromycin), and aminopenicillins (7).

A judicious use of antibiotics for COPD or asthma exacerbation is a provocation for clinician. In this context, the aim of our study was to identify the commonest bacterial pathogens and the preferred antibiotic for the treatment of the patients with recurrences for COPD and asthma exacerbations due to bacterial exacerbation of the disease.

MATERIALS AND METHODS

Study Design

A single-center, cross-sectional, retrospective study included recurrent COPD and asthma patients admitted in Iasi University Clinical Hospital of Pulmonary Diseases from North-East Romania from June 1, 2014 to May 31, 2019 (340 pulmonary, thoracic surgery and therapy beds). The study was approved by the Ethics Committee of "Grigore T. Popa" University of Medicine and Pharmacy of Iasi, Romania, and the Ethics Committee of Clinical Hospital of Pulmonary Diseases of Iasi, Romania (approval date 04.06.2020, respectively 22.01.2021).

Study Population and Data Collection

Patients of more than 40 years, with diagnosis of COPD, based on spirometry (with the ratio post-bronchodilator forced expiratory volume in one second (FEV1)/ forced vital capacity (FVC) < 0.70), or of asthma (with a 12%- or 200-mL improvement in FEV1 from the previous value), admitted in the hospital from June 2014 to May 2019, were screened to select patients with frequent hospitalizations.

The inclusion criteria were: 1) either COPD or bronchial asthma with specific diagnosis codes established by International Classification of Diseases 10th Revision (ICD-10): J44.0 – COPD with lower airway infection, J44.1 – COPD with acute, non-specific exacerbation, J44.8 – other specific COPD and J44.9 – non-specific COPD with all-cause rehospitalization; J45 and J46

diagnosis codes of asthma; 2) more than 2 exacerbations that needed hospital admission in the previous year; 3) at least one early re-admission (hospitalization in the first 30 days after previous discharge from hospital); 4) more than 24 hours hospitalization and 5) received at least one antibiotic during hospitalization.

The exclusion criteria were: admitted to the intensive care unit (ICU); pulmonary interstitial disease; cystic fibrosis diagnosis, pulmonary embolism; any type of cancer disease; under anti-tuberculosis treatment; and incomplete data in clinical record file.

Data extraction was from electronic and paper-based medical clinical records. The following data were collected: date of admission and discharge from hospital, length of hospitalization, age, gender, residence, comorbidities, COPD airflow severity based on spirometry, antibiotic use, bacterial pathogen from antibiogram, recommended treatment.

The main outcome was to identify the commonest bacterial pathogens isolated and the type of antibiotic chosen for the treatment.

Data Analysis

Demographic characteristics were summarized as a mean ± standard deviation (SD) for continuous variables and as a percentage of the group for categorical or dichotomous variables. The data were presented as absolute values and percentages for categorical variables

RESULTS

There were included 33 patients with frequent admissions in hospital (951 admissions in 5 years), 29 patients due to COPD exacerbations and 4 patients for asthma exacerbations (tab. I), with age between 44 years and 84 years, average age of 63 ± 9 years. The number of asthmatic patients is small because most of asthma exacerbations are not bacterial and we selected only patients with frequent hospital admissions due to bacterial exacerbation of the disease. The predominant comorbidity was arterial hypertension. Most of these patients 22 (67%) were on long-term oxygen treatment at home. Hospitalization average length was 12 ± 5 days, the longest hospitalization duration being of 47 days due to comorbidities.

TABLE I.

Patient characteristics (n=33)

Age (mean ± SD) (years)	63 ±9
Gender:	
Male	24 (73%)
Women	9 (27%)
Residence:	
Rural	25 (76%)
Urban	8 (24%)
Comorbidities:	
Hypertension	17 (52%)
Tuberculosis sequelae	20 (61%)
Heart failure	9 (27%)
Cor pulmonale	5 (15%)
Diabeties mellitus	5 (15%)
Atrial fibrillation	4 (12%)
COPD GOLD stage:	
GOLD 3	5 (82%)
GOLD 4	24 (18%)

Out of 948 sputum samples, 193 (20.35%) were positive culture sputum samples, 75 (39%) were *Streptococcus pneumoniae* and 98 (51%) were Gram Negative bacteria (fig. 1). There were no MRSA (methicillin resistant *Staphylococcus aureus*) in the sputum of these patients.

In each patient with asthma were identified in the sputum *Streptococcus pneumoniae* (6 samples in total), followed by gram negative bacilli (4 samples in total).

Each bacterium was with resistance at aminopenicillins and cephalosporins and the patients were treated with Ciprofloxacin, Gentamicin or Colistin according to antibiograms, with a medium of 10 days treatment.

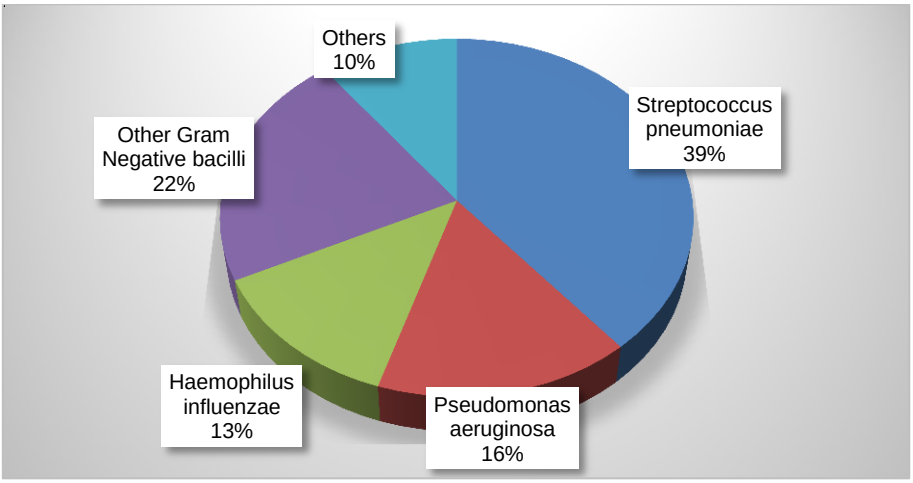

Fig. 1. Type of bacterial flora in positive sputum cultures. Other: *Klebsiella oxytoca, Serratia odorifera, Moraxella catarrhalis, Proteus spp., Escherichia coli.*

In COPD patients most of the time treatment was started with cephalosporins, rarely with aminopenicillins and changed on quinolones (levofloxacin *per os*, ciprofloxacin intravenously) most of the time, or colistin intravenously or associated with other antibiotic in aerosols. Other antibiotic that was recommended in small proportion were clarithromycin, gentamicin, clindamycin, trimethoprim/sulfamethoxazole. The identified bacteria showed resistance to aminopenicillins and frequently to cephalosporins 1st - 3rd generation, rarely sensitive at Ceftamil.

DISCUSSION

Our findings showed that bacteria in patients with frequent exacerbations can be hard to find and in most of the time these are resistant to usual antibiotics. The antibiogram of the sputum is the key point to stat antibiotics if the patient is stable, or to start with antibiotics according to previous bacteria identifications and antibiograms after sputum collection.

According to GOLD recommendations, the route of administration can be intravenous and the therapy days can be longer in COPD exacerbations. The choice of antibiotic should take into consideration also the local hospital/ region antimicrobial resistance map (5).

Chronic pulmonary diseases imply multidisciplinary approach, clear management plan for patient, closely treatment supervision and evaluation, comorbidity control, with intervention on modifiable risk factors like reduce tobacco and alcohol use, control blood pressure, environmental risk factors.

In Europe, the 2022 Eurostat report on respiratory diseases deaths in 2019 found them to be on 3rd place, after cardiovascular diseases deaths and lung cancer diseases

deaths. Romania is on 8th place at lung cancer death and second place on cardiovascular death in European Union. In our country population reporting that they suffering from asthma females were less than 2%, but more than males, for other chronic respiratory diseases than asthma our country reported less than 2% for males, but more than females (5).

World Health Organization found that COPD deaths was on the third place among global death causes in 2020 (6% of total deaths). These patients are fragile patients with frequent exacerbation due to pollution, cigarettes consumption, infections, other airway injuries, leading to frequent exacerbations with or without hospitalizations, disease progression, disease complications like heart failure, pulmonary embolism, frequent antibiotic consumption, negative health status and socio-economic effect (8, 9).

Literature studies identified chronic respiratory diseases exacerbations factors for asthma and COPD like poor adherence to treatment, pneumonia or other infections prior hospitalization, disease severity, oxygen therapy at home, and smoking. Moreover, pollution, climate change, aeroallergens, and pollen season, are other important factors for asthma exacerbations (1, 9).

Most existing studies in the literature analyses the duration of antibiotic therapy in exacerbations of chronic lung diseases such as COPD, asthma, cystic fibrosis, less the type of antibiotic used in these exacerbations, especially as the bacterial etiological agent could not be identified (10-13).

In a recent meta-analysis, authors investigate whether shorter courses of oral antibiotic treatment for asthma and COPD exacerbations are associated with different outcomes when compared with longer courses (14), in our findings most the treatment were a long one 10-14 days and without prolonged tine up to readmission in hospital.

We found that *Streptococcus pneumoniae* was frequent isolated in sputum in accordance with literature, *Hemophilus influenzae also* (4, 15-16). We found that *Pseudomonas aeruginosa* was isolated in increased number, frequent with resistance at usual antibiotic that are recommended in COPD/asthma exacerbation and the choice was Levofloxacin, Gentamicin, Colistin. The frequent isolation of the same bacteria at the same patient raise the possibility of colonization of the airway a long time.

Limitations of the study

Our date base is a small one, the number of patients with frequent chronic respiratory diseases (asthma and COPD) it is a small one, with a large number of hospitalizations.

CONCLUSIONS

COPD and asthma exacerbation can be a start to antibiotic stewardship because these patients are the most exposed to decompensations, increased hospital stay, increased treatment costs. Not all the time exacerbations are provoked by bacteria but it is hard to decide in some cases if it is just viral or other causes and clinicians are tempted to give antibiotics, leading to unnecessary use of antibiotics.

Together with a judicious use of antibiotics, adequate management of the disease, comorbidities, social and financial support of these patients is necessary to prevent frequent exacerbations.

FUNDING. This research was co-funded from the PhD doctoral program, from European Social Fund - the Human Capital Operational Program, Project /

THE INFLUENCE OF CO2 PRESSURE IN THE LAPAROSCOPIC OR ENDOSCOPIC APPROACH TO INCISIONAL HERNIAS (Abstract): Laparoscopic surgery is a transformative approach to surgical procedures, with significant benefits for patient recovery. However, the impact of carbon dioxide (CO2) pressure in laparoscopic incisional hernia surgery has been underexplored. **Materials and methods:** A retrospective analysis of 36 patients undergoing laparoscopic incisional hernia surgery over three years was conducted. Patients were categorized into lower and normal CO2 pressure groups. Post-operative factors, including pain, ileus, transit resumption, and hospital stay, were evaluated. **Results:** Patients in the normal CO2 pressure group reported significantly higher post-operative pain ($p = 0.05$) and a greater incidence of postoperative ileus ($p < 0.01$). Normal pressure patients also exhibited delayed transit resumption ($p < 0.01$). Hospital stay duration did not significantly differ ($p = 0.35$). **Conclusions:** Lower CO2 pressures during laparoscopic incisional hernia surgery are associated with lowered post-operative pain, improved gastrointestinal recovery, and a lower risk of ileus. These findings emphasize the potential benefits of optimizing CO2 pressure management to improve patient comfort and expedite recovery. This study underscores the multifaceted nature of post-operative outcomes, necessitating comprehensive assessments of surgical techniques and patient-specific factors. Enhanced CO2 pressure management holds promise for enhancing patient experiences and healthcare resource allocation. **Keywords:** LAPAROSCOPIC SURGERY, CO_2 PRESSURE, INCISIONAL HERNIAS, POST-OPERATIVE OUTCOMES, PAIN MANAGEMENT.

Surgical techniques have come a long way, and one of the most significant advancements in recent years is laparoscopic surgery or minimally invasive surgery. This approach has revolutionized patient care by making surgeries less painful, reducing hospital stays, and speeding up recoveries (1, 2). But there's a hidden factor that plays a crucial role in this process – the use of carbon dioxide (CO2) during surgery (3). The amount and pressure of CO2 used in the abdomen can have a profound impact on how patients feel after the surgery (4, 5).

The rationale for this study is grounded in the recognition that the ramifications of surgical interventions extend far beyond

the confines of the operating room, recovery playing an important medical but also economical role (6). While laparoscopy offers undeniable advantages, the nuances of CO2 pressure modulation have surfaced as a potential factor affecting post-operative well-being (7). Past research hints at the possibility that higher CO2 pressures, a characteristic of conventional laparoscopy, may not be benign (8), while other studies contradict this idea (9). They could be linked to a spectrum of post-operative issues, such as increased pain, delayed gastrointestinal recovery, and prolonged hospitalization.

The reason we're looking into this is that CO_2 pressure in surgery is a bit like a balancing act. On one hand, it's needed to create the space required for the surgeon to work inside the abdomen. On the other hand, using too much CO_2 pressure might not be good for the patient, and it could cause problems like more pain, slower recovery of the stomach, and a longer hospital stay (10). Some studies have suggested that if we're careful and use less CO_2 pressure, we might be able to avoid these problems and help patients get back to normal more quickly.

Our research is based on the idea that the balance between creating the right surgical environment and ensuring patient comfort is crucial. This study is motivated by the fact that we still have many questions about how CO_2 pressure in laparoscopic surgery affects patients after the incisional hernia operation. We aim to fill this knowledge gap by looking into how CO2 pressure influences things like post-operative pain, how quickly the bowels start working again, and how long patients stay in the hospital. Our goal is to understand how this can improve surgical practices and patient care. These have a significant impact on healthcare providers, hospital management, and, most importantly, the patients.

MATERIALS AND METHODS

The study involved a retrospective analysis of patients who underwent laparoscopic or endoscopic procedures for incisional hernias. These are patients that were treated for eventrations over a three-year period (2018-2021). These patients are part of a lager study comparing the approach of incisional hernias treated using either minimally invasive or classic intervention (11). To investigate the effects CO_2 pressure used in minimally invasive techniques used for treating incisional hernia, we evaluated post-surgery management of pain and recovery.

Thus, we measured the CO_2 pressure used during the intervention. We then defined two groups of patients, ones with lower values, for whom CO_2 pressures between 8 and 11 mmHg were used, and normal values, for whom CO_2 pressures between 12 and 15 mmHg were used. We evaluated pain presence at palpation, immediately after surgery, which was evaluated using a five-points pain scale, one being minimum and five being maximum. Other monitored aspects were: presence of pain after 12 and 24 hours, the need for antalgic medication, ICU post-intervention stay, and intestinal transit presence.

We used descriptive statistics (mean ± standard deviation or counts and percentages, depending on the type of variable). For comparing the two groups of patients we used nonparametric tests (Mann Whitney U for comparing continuous variables, or Chi-square test for nominal variables or Fisher test for 2x2 tables). Relative risk was calcu-

lated to assess the risk of complications, and 95% confidence intervals and p values were also calculated. Statistical significance was considered to be achieved when values o p lower than 0.05 were obtained.

RESULTS

Characteristics of the sample

We evaluated the basic characteristics of the patients included in the study (Table 1), and compared them among the two created groups. The lower values group of patients had a number of 26 cases (72.2%) and the group of patients with normal values of CO2 pressure had 10 cases (27.8%). We provide an analysis of the demographic and clinical characteristics of patients in the study, highlighting the differences or lack thereof between the lower and normal CO_2 pressure groups (tab. I).

TABLE I.

Characteristics of the sample

	Total (36)	Lower pressure (26)	Normal pressure (10)	p-value
Age				
Mean ± SD	50.3±13.7	51.1±12.5	48.4±17.1	0.67
Sex				
Male	19 (52.8%)	15 (57.7%)	4 (40%)	0.46
Female	17 (47.2%)	11 (42.3%)	6 (60%)	
Environment				
Urban	28 (77.8%)	18 (69.2%)	10 (100%)	0.07
Rural	8 (23.2%)	8 (30.8%)	0 (0%)	
Weight				
Mean ± SD	90.4±14.9	91.7±15.6	87±13.0	0.48
Localization				
Supraumbilical	18 (50%)	18 (69.2%)	0 (0%)	<0.01
Umbilical	6 (16.7%)	6 (23.1%)	0 (0%)	
Sub umbilical	10 (27.8%)	0 (0%)	10 (50%)	
Inguinal	2 (5.5%)	2 (7.7%)	0 (0%)	
Size of the defect (cm)				
Mean ± SD	10.03±4.8	10.44±5.7	9.7±4.1	0.95

The mean age of the patients in the study was 50.3 years with a standard deviation of 13.7. There was no statistically significant difference in mean age between patients who underwent laparoscopic surgery with lower CO_2 pressure (51.1±12.5) and those with normal CO_2 pressure (48.4±17.1) groups (p=0.67), indicating that age was not a significant confounding factor in the study. The study included 19 male patients (52.8%) and 17 female patients (47.2%). The proportion of male patients was slightly higher in the lower CO_2 pressure group (57.7%) compared to the normal CO_2 pressure group (40%), but this difference was not statistically significant (p=0.46). In terms of the patient's environmental setting, 77.8% of patients came from urban areas, while 23.2% came from rural areas. Interestingly, all patients in the normal CO_2 pressure group were from urban areas, whereas 30.8% of patients in the lower pressure group came from rural areas. Considering that the pa-

tients come from South-eastern part of Romania, namely Constanta County, this is a normal distribution, as the County has, according to the latest data, approximately 70% of the people living in urban areas. The difference in the distribution of patients from rural and urban settings between the two CO2 pressure groups approached statistical significance (p=0.07). The mean weight of patients in the study was 90.4 kg with a standard deviation of 14.9. There was no statistically significant difference in mean weight between the lower CO_2 pressure group (91.7±15.6) and the normal CO_2 pressure group (87±13.0) (p=0.48), suggesting that weight did not significantly differ between the groups.

Regarding the localization of incisional hernias, it's worth noting that a statistically significant difference was observed between the two CO_2 pressure groups. All patients with supraumbilical hernias were in the lower CO_2 pressure group, while the normal CO2 pressure group had no cases of supraumbilical hernias. This difference was highly significant (p<0.01). The mean size of the hernia defect was 10.03 cm with a standard deviation of 4.8. There was no statistically significant difference in the mean size of the defect between the lower CO_2 pressure group (10.44±5.7) and the normal CO_2 pressure group (9.7±4.1) (p=0.95), indicating that the size of the defect did not significantly vary between the two groups.

We analyzed the outcome of the interventions using three major criteria. The first one is related to actions taken during the intervention (lidocaine infiltrations) and the duration of the procedure. The second criterion was related to the post-surgery pain management and the last criterion was related to post-intervention recuperation.

Characteristics of the intervention

The results are depicted in table II. The mean duration of the surgical intervention in the study was 100.8 minutes with a standard deviation of 30.8. There was no statistically significant difference in the mean duration between patients who underwent laparoscopic surgery with lower CO_2 pressure (98.1±30.8 minutes) and those with normal CO_2 pressure (108±31.2 minutes) groups (p=0.4). This suggests that the duration of the surgical procedure did not significantly differ between the two CO_2 pressure groups. We observed a difference in the use of lidocaine infiltrations during the surgical procedures. A significant difference was observed in the use of lidocaine infiltrations during the surgical procedures. In the lower CO_2 pressure group, 38.9% of patients received lidocaine infiltrations, while all patients (100%) in the normal CO2 pressure group received lidocaine infiltrations. The relative risk was 6.5 (CI 95% 2.63-16.01), indicating a substantial disparity in the use of lidocaine infiltrations between the two CO_2 pressure groups. This difference was highly statistically significant (p<0.01).

TABLE II.

Intervention characteristics

	Total (36)	Lower pressure (26)	Normal pressure (10)	p-value
Duration of the intervention (minutes)				
Mean ± SD	100.8±30.8	98.1±30.8	108±31.2	0.4
Lidocaine infiltrations				
No	22 (61.1%)	22 (84.6%)	0 (0%)	<0.01
Yes	14 (38.9%)	4 (15.4%)	10 (100%)	

The mean pain intensity reported by patients after surgery was 2.03 (on a scale from 1 to 5, 1 being no pain and 5 being unbearable pain), with a standard deviation of 1.05. There was a statistically significant difference in mean pain intensity between patients who underwent laparoscopic surgery with lower CO_2 pressure (1.77±0.8) and those with normal carbon dioxide pressure (2.7±1.4) groups (p=0.05). This suggests that patients in the normal CO_2 pressure group experienced higher pain intensity after surgery compared to those in the lower CO_2 pressure group.

TABLE III.
Pain characteristics

	Total (36)	Lower pressure (26)	Normal pressure (10)	p-value
Pain Intensity after surgery				
Mean ± SD	2.03±1.05	1.77±0.8	2.7±1.4	0.05
Pain at 12 hours				
No	21 (58%)	17 (65.4%)	4 (40%)	0.26
Yes	15 (41.7%)	9 (34.6%)	6 (60%)	
Pain at 24 hours				
No	25 (69.4%	18 (69.2%)	7 (70%)	1
Yes	11 (30.6%)	8 (30.8%)	3 (30%)	
Analgesic post-surgery treatment				
No	22 (61.1%)	18 (69.2%)	4 (40%)	0.14
Yes	14 (38.9%)	8 (30.8%)	6 (60%)	

At twelve hours post-surgery evaluation, a difference was observed in the incidence of pain reported by patients. In the lower carbon dioxide pressure group, 41.7% of patients reported pain, while in the normal carbon dioxide pressure group, 60% of patients reported pain. The relative risk for a patient on whom a $_{CO2}$ pressure between 12 and 15 mmHg was used to experience pain, compared to a patient for whom a CO_2 pressure of no more than 11 mmHg was used was 1.73 (C.I. 95% = 0.83-3.60). The result did not reach statistical significance (p=0.26), indicating that the incidence of pain at 12 hours did not significantly differ between the two CO2 pressure groups.

The incidence of pain reported by patients at 24 hours post-surgery also demonstrated no statistically significant difference between the lower and normal CO_2 pressure groups. In the lower CO_2 pressure group, 30.6% of patients reported pain at 24 hours, while in the normal CO_2 pressure group, 30% of patients reported pain (p=1), with relative risk of 0.97 (C.I. 95% = 0.32-2.95).

The use of analgesic post-surgery treatment revealed a difference between the two CO_2 pressure groups. In the lower CO_2 pressure group, 38.9% of patients received analgesic treatment, while in the normal CO_2 pressure group, 60% of patients received analgesic treatment. Although this difference did not reach statistical significance (p=0.14), it indicates a potential disparity in the need for post-surgery analgesic treatment between the two groups. The relative risk was 1.95 (C.I. 95% = 0.90-4.19).

Post-surgery evolution

A significant difference was observed in

the incidence of postoperative ileus between patients who underwent laparoscopic surgery with lower CO_2 pressure and those with normal CO_2 pressure. In the lower CO_2 pressure group, 7.7% of patients experienced postoperative ileus, while in the normal CO2 pressure group, 60% of patients experienced this complication. Thus, the relative risk was 7.8 (C.I. 95% =1.87-32.41). This indicates a significantly higher risk of having post-surgery ileus in patients within the normal CO_2 pressure group. This difference was highly statistically significant ($p<0.01$).

TABLE IV.

Post-surgery evolution

	Total (36)	Lower pressure (26)	Normal pressure (10)	p-value
Postoperative ileus				
No	28 (77.8%)	24 (92.3%)	4 (40%)	<0.01
Yes	8 (22.2%)	2 (7.7%)	6 (60%)	
Days to transit resuming				
1	12 (33.3%)	10 (38.5%)	2 (20%)	<0.01
2	16 (44.4%)	14 (53.8%)	2 (20%)	
3	8 (22.2%)	2 (7.7%)	6 (60%)	
Days of stay in ICU				
1	12 (33.3%)	8 (30.8%)	4 (40%)	0.65
2	7 (19.4%)	6 (23.1%)	1 (10%)	
3	17 (47.2%)	12 (46.2%)	5 (50%)	
Days of hospitalization				
Mean ± SD	2.72±0.9	2.62±0.85	3±1.15	0.35

The time to resumption of transit (bowel function) following surgery showed a statistically significant difference between the two CO_2 pressure groups. In the lower CO_2 pressure group, 38.5% of patients resumed transit within 1 day, 53.8% within 2 days, and 7.7% within 3 days. In contrast, in the normal CO_2 pressure group, only 20% of patients resumed transit within 1 day, 20% within 2 days, and 60% within 3 days. These differences were highly statistically significant ($p<0.01$), indicating a substantial delay in transit resumption in the normal CO2 pressure group.

There was no statistically significant difference in the number of days patients spent in the Intensive Care Unit (ICU) between the lower and normal CO_2 pressure groups. The distribution of patients spending 1, 2, or 3 days in the ICU was similar between the two groups, and the p-value was 0.65.

The mean length of hospitalization for all patients was 2.72 days, with a standard deviation of 0.9. There was no statistically significant difference in the mean length of hospitalization between patients who underwent laparoscopic surgery with lower CO_2 pressure (2.62±0.85 days) and those with normal CO_2 pressure (3±1.15 days) groups ($p=0.35$). This suggests that the overall length of hospitalization did not significantly differ between the two CO2 pressure groups.

DISCUSSION

This study delves into the critical question of how the management of CO_2 pres-

sure during laparoscopic surgery can impact postoperative outcomes in patients with incisional hernias.

The analysis of demographic and clinical characteristics, including age, sex, environment, weight, hernia localization, and size of the defect, did not show significant differences between the lower CO_2 pressure and normal CO_2 pressure groups. These findings suggest that patients in both groups were generally comparable in terms of these baseline factors, reducing the potential for confounding variables. Also, we observe that there are no disparities between patients, as observed in other studies where, for example environment or sex played important roles in diagnosis capacities (12, 13).

One of the key findings of this study was the significant difference in postoperative pain intensity between the two CO_2 pressure groups. Patients in the normal CO_2 pressure group reported higher postoperative pain intensity compared to those in the lower CO_2 pressure group. This finding raises important questions about the potential role of CO_2 pressure in influencing pain perception following laparoscopic surgery. These findings are in line with previously published papers on the topic (14).

Additionally, the data indicate a substantial difference in the use of lidocaine infiltrations between the two groups. A significantly higher proportion of patients in the normal CO2 pressure group received lidocaine infiltrations as part of their pain management strategy. The increased use of lidocaine in the normal V pressure group may have contributed to the observed differences in pain intensity. This usage of lidocaine has the potential of alleviating the pain immediately after surgery (15), and also to influence the need of post-surgery analgesic medication (16, 17), even an effect on chronic pain being observed (18). When referring to pain management, there is a real endeavor in identifying also non-pharmaceutical methods of reducing it, not only post-surgery (19) but also in other types pain-inducing interventions (20).

Postoperative ileus, a common complication following abdominal surgery, was significantly more prevalent in the normal CO_2 pressure group. Patients in this group experienced a substantially higher incidence of postoperative ileus, which is consistent with previous literature suggesting that higher intra-abdominal pressures, may impact gastrointestinal motility and contribute to ileus (21, 22). Moreover, the time to resumption of bowel function, measured as days to transit resuming, was significantly prolonged in the normal CO_2 pressure group. The delayed transit resumption in this group may be attributed to the impact of higher CO_2 pressures on gastrointestinal function, as well as the increased incidence of postoperative ileus. These findings emphasize the potential clinical importance of CO_2 pressure management in laparoscopic surgery to mitigate postoperative ileus and promote earlier recovery of bowel function. The length of hospitalization and the number of days spent in the Intensive Care Unit (ICU) did not show significant differences between the two CO_2 pressure groups. While both groups had similar lengths of hospital stay and days in the ICU, these parameters may be influenced by various factors beyond CO_2 pressure, such as surgical technique, patient recovery, and hospital protocols (23).

The findings from this study have several clinical implications. The higher postoperative pain intensity, increased inci-

dence of postoperative ileus, and delayed transit resumption observed in the normal CO_2 pressure group underscore the potential benefits of carefully managing CO_2 pressures during laparoscopic surgery. Reduced CO_2 pressure may contribute to improved postoperative pain control and a faster return to normal gastrointestinal function. These findings should encourage further research into the optimization of CO_2 pressure levels to enhance patient outcomes in laparoscopic surgery.

This study has several limitations, mainly the relatively small sample size. Larger prospective studies are needed to confirm and expand upon these findings. Additionally, other variables, such as surgical techniques, perioperative care, and patient factors, may have influenced the outcomes studied and should be considered in future investigations.

CONCLUSIONS

Carbon dioxide pressure is a critical factor in laparoscopic and endoscopic approaches to incisional hernias. Surgeons must carefully consider the balance between optimal visualization, patient comfort, and surgical challenges. The findings suggest that a lower carbon dioxide pressure remains a reliable choice for creating a conducive working space. However, the use of elevated pressures should be approached cautiously due to the potential for increased dissection difficulty and patient discomfort. Similarly, while low pressures might alleviate pain and discomfort, the associated risks of bleeding and compromised visualization cannot be ignored.

This study contributes to a deeper understanding of the impact of carbon dioxide pressure on surgical outcomes and patient experiences in the context of incisional hernia procedures. Further research could explore strategies to mitigate the challenges posed by elevated carbon dioxide pressures or investigate innovative approaches to address issues related to low pressures.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest and they received no funding.

BREAST FIBROADENOMAS: ULTRASOUND APPEARANCE AND POTENTIAL ASSOCIATION WITH PERIPHERAL VEIN THROMBOSIS (Abstract): The **aim** of this study was to characterize the ultrasound appearance of breast fibroadenomas and explore a potential association with peripheral vein thrombosis. **Materials and methods:** We retrospectively studied between January 2021 and December 2022 the imaging records and reports of 159 women with fibroadenomas who underwent breast ultrasound (US) with an 11-18 MHz linear transducer and 7 of them lower extremity US for suspicion of peripheral vein thrombosis with an 11-18 MHz linear or a 3-6 MHz curved transducer. **Results:** We found a total of 293 fibroadenomas, and the most frequent pattern was: isoechoic (69.62% lesions), homogenous (77.47% lesions), with well-defined (100%), macrolobulated margins (51.88%), oval-shaped (95.22% tumors), with a Solbiati index greater than or equal to 2 (51.19%), without Doppler signal (73.72%). We studied the correlation between the Doppler signal and contour pattern, the number of lobulations, and the Solbiati index using a function in Python, and we found the following results: the dimensions of the fibroadenoma (r = 0.117438) and the number of lobulations (r = 0.282) have a positive correlation, but the Solbiati index (r = -0.012) and contour pattern (r = -0.243945) have a negative correlation with the presence of the Doppler signal. The association of multiple breast fibroadenomas with peripheral vein thrombosis was rare (7.46% cases). We monitored 147 patients with simple fibroadenomas every six months for two years, and none of them had a significant variation in the dimensions. **Conclusions:** The association of multiple breast fibroadenomas with peripheral vein thrombosis was rare, so we considered it to be a random association. In our study, the most frequent pattern of fibroadenomas was isoechoic, homogenous, oval-shaped lesions with macrolobulated margins, a Solbiati index greater than or equal to 2, and no Doppler signal. According to our experience, we offered, for typical fibroadenomas, the option of conservative management. A fine needle biopsy was advised in one case with atypical-appearance lesions at ultrasound.
Keywords: FIBROADENOMAS, VEIN THROMBOSIS, ULTRASOUND.

INTRODUCTION

Fibroadenomas are benign lesions with minimal or no malignant potential (malignant transformation 0.01-0.3%), frequent between ages 15 and 35, with predilection for the upper outer quadrant, and a slightly

variable dimension in time or with the period. There are at least two special types of breast fibroadenomas: complex fibroadenomas (which can grow over time) and giant fibroadenomas (growing quickly to a diameter larger than 5 centimeters) (1). Multiple fibroadenomas account for 20% of breast fibroadenoma cases, and their management presents particular challenges because they may have other associated diseases and it is difficult to follow up on every single lesion (2, 3).The cause of fibroadenomas is not known, but the relationship with ovarian hormones is considered important. Simple fibroadenomas are predominantly encountered in women of reproductive age (the incidence is 7-13% in women from adolescence through the mid-20s) (4). The hormonal fluctuations during the menstrual cycle, puberty, pregnancy, menopause, and oral contraceptives increase the risk of fibroadenomas, may stimulate fibroadenomas' growth, and increase the risk for peripheral vein thrombosis (2, 5). Typically, ultrasound depicts a round or ovoid, homogeneous, hypoechoic, well-circumscribed, or macrolobulated mass; intralesional calcification in (~10% of cases) and a thin echogenic rim (pseudocapsule) may be seen (6). Mammography and MRI contribute to the diagnosis (7, 8). When a lesion has the typical features of a fibroadenoma on ultrasound and there are no clinical issues, it can be safely followed. When lesions enlarge or have atypical imaging findings, an ultrasound-guided core biopsy will give a diagnosis (9).

MATERIALS AND METHODS

We retrospectively studied between January 2021 and December 2022 the imaging records and reports of 159 women with fibroadenomas who underwent B mode and Doppler mode breast US with an 11-18 MHz linear transducer and 7 of them lower extremity US for suspicion of deep vein thrombosis with an 11-18 MHz linear or a 3-6 MHz curved transducer (which provides a deeper field view) using a General Electric Voluson E6 ultrasound machine.

Breast US study protocol included bilateral examination with transversal, longitudinal, radial, and antiradial sections of the breast and evaluation of the axillary, subclavian, supraclavian, and internal mammary regions; the patient is lying down in supine position (with right and left oblique rotation in case of large breasts), with the hands above the head (for better exposure of the breast and evaluation of internal mammary and axillary regions), and with the hands nearby the body (for the examination of subclavian and supraclavian regions). For a better visualization of the pathology, the focal zone of the probe must include the lesion, the power of the ultrasound waves, time gain compensation, and gain carefully adjusted for optimal visualization of the deep structures of the breast, for compensating the rapid attenuation of the waves when high frequencies are used, and for well-differentiating the solid and cystic lesions, respectively. The compression of the lesions with the transducer is useful to determine the hardness of the solid ones and to demonstrate the mobility of the internal echoes of the cysts.

The ultrasound report must include the exact location of the lesions, echogenicity (compared with the fatty tissue), number, dimensions (at least two: the longest dimension and the transversal dimension), structure, compressibility, associated acoustic changes, and Doppler signal characteristics. This study was focused on lesion number,

echogenicity, the longest dimension (L), ratio between the longest (L) and the transversal (T) dimensions (L/T ratio, Solbiati index), structure, presence and location (central and peripheral) of the Doppler signal, and lesion growth over time.

If after the first ultrasound examination the patient had lesions with a typical pattern for fibroadenomas, we indicated follow-up at a 6-month interval, and if the lesions did not grow more than 10%, we considered them to be stable, and the diagnosis of fibroadenoma was made with confidence. Conservative treatment with follow-up every 6 months for 2 years was applied. If, in time, one of the fibroadenomas grows more than 10%, we return to a 6-month follow-up for another two years. If the lesions have an odd feature (anechoic components, micro calcifications, poorly defined margins), the patient was referred to a fine needle biopsy to correlate with morpho-pathology.

Ultrasound examination for lower limb deep vein thrombosis was extended from the common femoral vein to the anterior tibial, posterior tibial, and peroneal veins, with transversal and longitudinal sections and segmental compression every 2 cm. The patient lies down in supine position with the head elevated to help with venous pooling, and the examined leg is externally rotated with the knee slightly bent (for better access to the femoral and popliteal veins) (10, 11).

RESULTS

We studied 159 women, age range17 to 74 years, who had 293 fibroadenomas, among them 67 had multiple fibroadenomas, and we studied the US pattern of the lesions, the associated breast diseases (fibrocystic breast disease, mammary duct ectasia) and peripheral vein thrombosis (which was found in 5 cases).Most of the woman (121 -76.10%) had at diagnosis ages between 26 and 49 years, accordingly to the literature (1)(fig. 1).

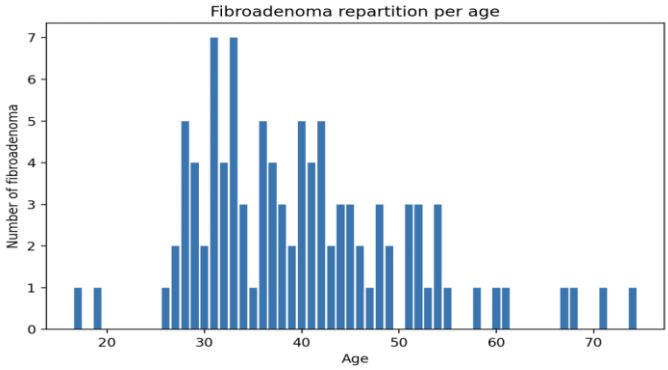

Fig. 1. Number of fibroadenomas - repartition per age

The average number of fibroadenomas was 1.85 per person, and the highest number of lesions was in the case of a 21-year-old woman (7 lesions). Among the 159 patients, we found 92 (57.86%) (age range 27 to 60 years) with a single fibroadenoma and 67 (42.14%) (age range 27 to 50 years) with multiple fibroadenomas, most of them associating fibrocystic breast disease (61.95% and 76.11%, respectively), and 62 (38.99%) presented mammary duct ectasia.

In the case of 7 patients with multiple

fibroadenomas, we also depicted lower extremity edema and referred them to the cardiologist, who found at clinical examination unilateral lower extremity edema, tenderness, erythemas or cyanosis, dilated superficial veins, palpable thrombotic veins, and suspected deep vein thrombosis of the lower extremity confirmed by B mode and Doppler mode US in 5 cases. The association of multiple breast fibroadenomas with peripheral vein thrombosis was rare (7.46% cases), so we considered it to be a random association, results that are similar to the literature data (12) (fig. 2).

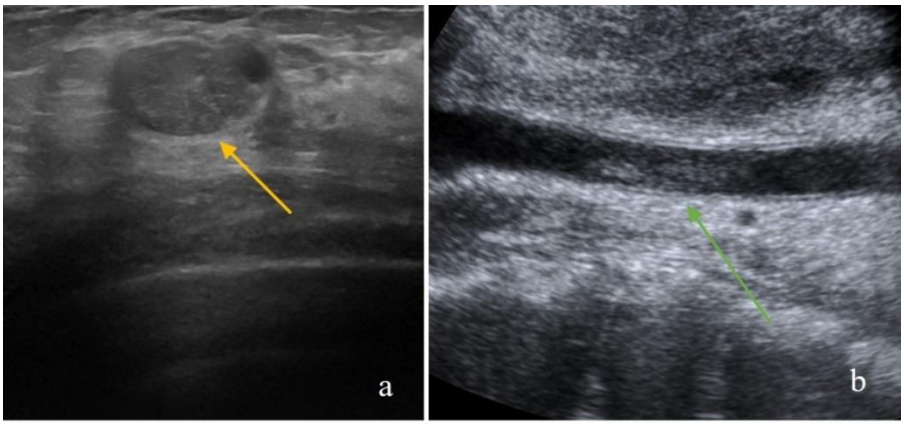

Fig. 2. B mode breast ultrasound- isoechoic, macrolobulated, oval shaped inhomogeneous (yellow arrow) fibroadenoma (a); B mode thigh ultrasound femoral vein thrombosis

The most frequent pattern of fibroadenomas was: isoechoic (204-69.62% lesions), homogenous (227-77.47% lesions), with well-defined (100%), macrolobulated margins (152-51.88%), oval-shaped (279-95.22%) tumors, with a Solbiati index greater than or equal to 2 (150-51.19%), and without Doppler signal (216-73.72%). A small number of tumors were round 14 (4.78%), with Solbiati index smaller than 2 (142-48.46% cases), microlobulated (42-14.33%) or regular (99-33.79%) margins, hipoechoic (89-30.38%), and inhomogenous structure in 66-22.29% of lesions (the most special types of inhomogeneities being macrocalcifications 4.09%, microcalcifications 1.70%, or anechoic inclusions 1.70%). In our study, most of the tumors had the largest diameter smaller than 2 cm (255-87.03%), and only 38 (12.97%) tumors had L diameter between 2 and 7 cm; 77 (26.28%) had Doppler signal present (mostly peripheral, 47-16.04%) (fig. 3). Microlobulated margins (found in 14.33% of the tumors) are considered in the literature a problem for a confident diagnosis of fibroadenoma, but the microlobulated lesions did not grow over time, so in the end, this pattern was also included in benign lesion features (6). No lymphadenopathies were found.

One special case was a 27-year-old female who had four hypoechoic lesions: two lesions were simple fibroadenomas (followed-up at a 6-month interval for 24 months), and two mases had an uncertain appearance (hypoechoic, inhomogeneous, one of them containing an irregular anechoic area, and the other one with microcalcifications) and were referred to a fine needle biopsy, which established the diagnosis of complex fibroadenomas (fig. 4).

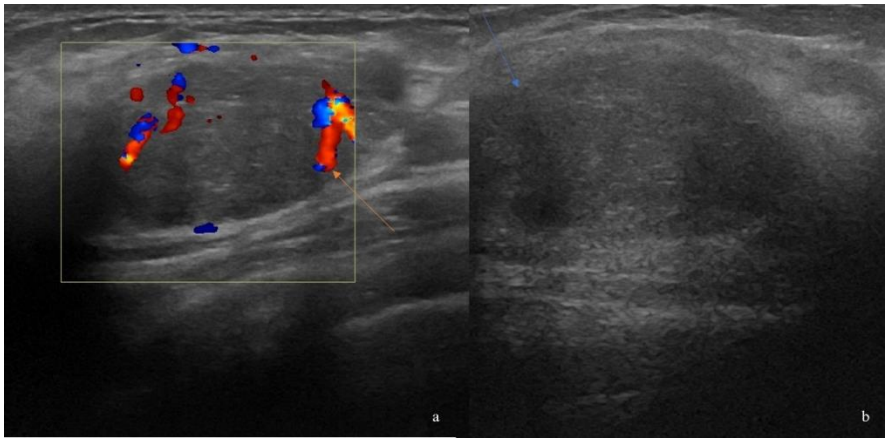

Fig. 3. B and Doppler mode breast ultrasound: isoechoic, well-circumscribed fibroadenoma with central and peripheral Doppler signal (orange arrow) (a); B mode breast ultrasound: isoechoic fibroadenoma, with macrolobulated margins (blue arrow) (b)

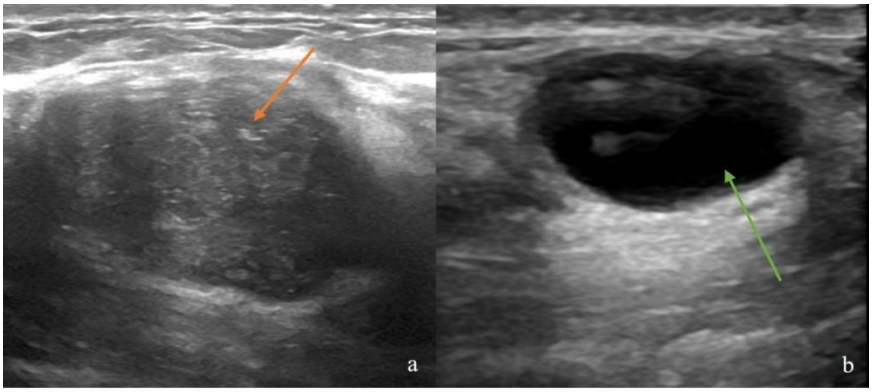

Fig. 4. B and Doppler mode breast ultrasound, BI-RADS 4a lesions: hypoechoic, macrolobulated, oval shaped lesion, with microcalcifications (orange arrow) (a); inhomogeneous hypoechoic, microlobulated, oval shaped lesion, containing an irregular anechoic area (green arrow) (b)

We studied the correlation between the Doppler signal and the following features of the lesions: contour pattern (regular or lobulated margins), number of lobulations, dimensions, and length-to-thickness ratio using a function in Python that has the following definition: correlation is used to summarize the strength and direction of the linear association between two quantitative variables. It is denoted by r and has values between -1 and +1. A positive value for r indicates a positive association, and a negative value for r indicates a negative association. We found the following results: lobulated margins (r = -0.243945), the number of lobulations (r = 0.282), dimensions (r = 0.117438), and length-to-thickness ratio (r = -0.012), and we concluded that the larger the dimensions of the fibroadenoma and the higher the number of lobulations will corre-

late with the presence of the Doppler signal; the length-to-thickness ratio and contour pattern have a negative correlation with the Doppler signal.

To correlate Doppler signal with three variables at once (contour pattern, number of lobulations, and dimensions), we used the algorithm Ordinary Least Squares Regression, and the most interesting of all results was the coefficient (Coef), which suggests a moderately positive correlation between Doppler signal and the number of lobulations (tab. I).

According to all the features we had studied, we concluded that 182 (62.12%) patients had simple fibroadenomas, which had to come for follow-up every 6 months for two years; nine (3.07%) patients with complex fibroadenoma and one (0.34%) patient with a giant fibroadenoma came every 3 months for 6 months, and then at a 6-month interval, and one (0.34%) patient with an uncertain lesion was referred to a fine needle biopsy, which confirmed the diagnosis of complex fibroadenoma (13). The compliance for follow up was good enough: we monitored 158 lesions for at least 2 years; among them most fibroadenomas (116-73.42%) had stationary dimensions, 23 (14.56%) fibroadenomas were increasing in size, 14 (8.86%) fibroadenomas had decreasing sizes, 5 (3.16%) fibroadenomas had variable size over time (increasing and decreasing) (fig. 6).

TABLE I.

Correlation between Doppler signal and contour pattern, number of lobulations and dimensions with Ordinary Least Squares Regression algorithm

Doppler signal	Coef.	Std. errs.	T
Dimensions (cm)	0.048	0.049	0.981
Contour pattern	-0.048	0.233	-0.207
No. of lobulations	0.379	0.167	2.267

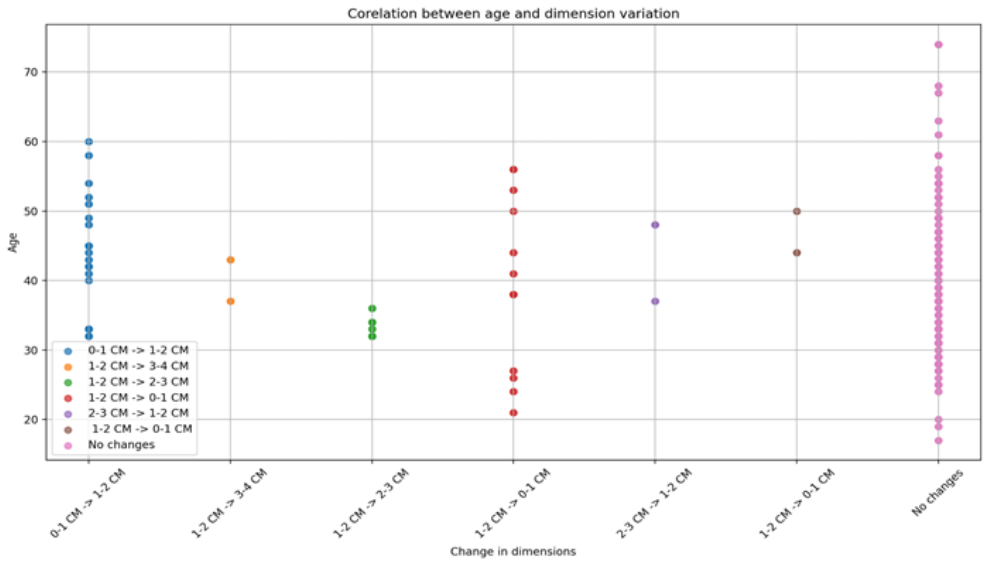

Fig. 6. Correlation between age and dimension variation over time

DISCUSSION

The most frequent pattern of fibroadenomas was isoechoic, homogenous oval-shaped lesions with a Solbiati index greater than or equal to 2, well-defined margins, and no Doppler signal, which was similar to the literature data (4). Other features of the lesions were discordant with the literature data: macrolobulated margins (51.88%) were more frequent than regular margins (33.79%) (1).

The association between multiple breast fibroadenomas and peripheral vein thrombosis was rare (5-7.46% cases), so we considered it to be a random association, despite the fact that both lesions have hyper estrogenism among the etiology (12).

Most of the lesions were homogeneous, slightly inhomogeneous, or contained macrocalcifications; only 10 (3.38%) tumors had microcalcifications or anechoic inclusions, which raised the suspicion of complex fibroadenomas and indicated follow-up at a 3-month interval (nine cases) and a fine needle biopsy (in one case) (4).

Most of the tumors had the largest diameter smaller than 2 cm (87.03%), and the number of tumors with diameters between 2 and 7 cm was fewer (12.97%), according to the literature data (9). The only lesion considered to be a giant fibroadenoma was an isoechoic 7/3 cm tumor with central Doppler signal present in the case of a 29-year-old woman, which was followed up initially at 3 months with insignificant growth (0.5 cm) over this period of time.

We studied the correlation between Doppler signal and contour pattern, number of lobulations, largest dimensions, and length-to-thickness ratio using a function in Python; lobulated margins ($r = -0.243945$) and Solbiati index ($r = -0.012$) have a negative correlation, but the number of lobulations ($r = 0.282$) and lesions' largest dimension ($r = 0.117438$) have a positive correlation with the presence of Doppler signal.

In terms of follow-up, our data were similar to those in the literature (13). We managed to monitor the simple fibroadenomas (according to the compliance of the patients) in 147 cases every 6 months for two years, and none of them had a significant variation of the dimensions in order to raise diagnostic issues; nine with complex fibroadenomas and one with giant fibroadenoma came every 3 months for 6 months, and then at a 6-month interval for two years, and one patient with complex fibroadenomas was referred to a fine needle biopsy.

CONCLUSIONS

The association of multiple breast fibroadenomas with peripheral vein thrombosis was rare, so we considered that a random association.

In our study, the most frequent pattern of fibroadenomas was an isoechoic, homogenous oval-shaped lesion with a Solbiati index less than 2, well-defined macrolobulated margins, and no Doppler signal. A small number of tumors were round, microlobulated, hypoechoic, with inhomogeneous structure due to macrocalcification, microcalcifications, or anechoic inclusions, with a Solbiati index larger or equal to 2, and a Doppler signal present, mostly in the periphery of the lesions. Most of the tumors were smaller than 2 cm; less frequently, we encountered tumors with the largest diameters between 2 and 7 cm.

We found, using a function in Python, that the Doppler signal has a negative correlation with lobulated margins and the L/T ratio and a positive correlation with the

number of lobulations and lesions' largest dimension.

According to our experience when offered the option of conservative management, in our study, most women preferred follow-up and not biopsy. A fine needle biopsy was advised in one case with atypical-appearance lesions at ultrasound.

EVOLUTION OF INFLAMMATORY MARKERS IN PATIENTS WITH PROSTHETIC JOINT INFECTION TREATED WITH *STIMULAN* (Abstract): Total hip arthroplasty is a commonly performed procedure with a known risk of postoperative infection. Diagnosing an infection after total hip arthroplasty can be challenging, as there are no consistently reliable preoperative tests for infection in patients requiring a revision arthroplasty. This study **aimed** to assess the common investigative methods for diagnosing infection at the site of a previous arthroplasty and the evolution of these biomarkers in patients treated with biocomposite and traditional surgical treatment. **Materials and methods:** We conducted a prospective analysis of pre- and postoperative investigations used to diagnose infection in 44 patients admitted from January 2017 to September 2023 at the "Sf. Apostol Andrei" County Clinical Emergency Hospital of Galati. **Results:** Our study group included 31.81% women and 68.19% men. The most common symptoms experienced by patients were pain and functional incapacity of the lower limb. Only ESR and CRP were elevated in all patients at admission. Their values decreased postoperatively, and determinations at two and six weeks postoperatively showed normalization of ESR, while CRP remained slightly elevated. **Conclusions:** The biological modifications were generally typical when considering the preoperatory moment, with notable rapid improvement in inflammatory status within the first six weeks post-surgery. The novel approach that includes bio composites seems to have major clinical impact on the future management of prosthetic joint infections given the cure rate and the general evolution. **Keywords:** PROSTHETIC JOINT, INFLAMMATORY MARKERS, INFECTION, BIOCOMPOSITE.

After joint replacement surgeries, most patients find relief from preoperative pain and disability. While the surgeries are generally successful and lead to high patient satisfaction, it's important to be aware of the associated risks. Infection is one of the

most concerning complications of this type of operation.

In addition, it can be challenging to confirm a diagnosis of prosthetic joint infection (PJI) after total hip arthroplasty (THA). Patients with this type of infection often do not display typical signs and symptoms, such as fever, chills, or elevated white blood cell count.

In some cases, microorganisms enter the joint during the insertion of the prosthesis (direct inoculation), while in others, bacteria travel to the joint through the bloodstream (hematogenous spread).

Some bacteria, like coagulase-negative staphylococci, have low virulence and can persist due to prosthetic material and biofilm. These infections usually cause a chronic low-grade infection with few systemic symptoms. On the other hand, diseases caused by high-virulence organisms, such as Staphylococcus aureus, can lead to severe conditions like septicemia and bacterial endocarditis (1).

Staphylococci species are the most common causative organisms of joint infections, followed by streptococci, enterococci, and Gram-negative bacteria. Gram-negative bacteria account for about 8% of cases (2).

The erythrocyte sedimentation rate (ESR) and white blood cell (WBC) count are said to have low reliability as indicators of prosthetic joint infection (3). However, these indicators can be influenced by age and medical conditions. An ESR greater than 30 mm/h and a CRP greater than 10 mg/L are considered elevated levels (4). The sensitivity and specificity of ESR and CRP can vary widely in the available literature. If both the ESR and CRP are normal, however, the probability of infection is around 3% (5).

This research is part of a larger study evaluating the efficacy of using an antibiotic-loaded bio composite (*Stimulan*) in addition to conventional treatment. One of the objectives of this original research was to evaluate the inflammatory biologic profile and its evolution in this category of patients. To our knowledge, this is the first research of its kind in our country, with a major clinical impact on the future management of prosthetic joint infections.

MATERIALS AND METHODS

We carried out a retrospective study from January 2017 to September 2023 at the "Sf. Apostol Andrei" County Clinical Emergency Hospital of Galati. Our research involved patients who were hospitalized for hip arthroplasty.

During the specified period, 44 out of 4,244 hip arthroplasty surgeries were included in this study. The study focused on patients with hip arthroplasty-related infections who were treated with the biocomposite *Stimulan* in addition to the classical surgical treatment.

Patients with chronic inflammatory conditions, those with malignancy, or patients who had previously received antibiotic treatment before surgery were excluded based on the criteria.

Data on age, gender, BMI, laboratory results, type of intervention, progression, and post-surgery outcomes were collected.

A patient was considered to have an infected THA if they met any of the following criteria (6):

1. Presence of a sinus tract communicating with the prosthesis

2. Isolation of a pathogen by culture from two separate tissue or fluid samples obtained from the affected prosthetic joint

3. Any four of the following six criteria:

a. Elevated serum erythrocyte sedimentation rate (ESR) or serum C-reactive protein (CRP) concentration

b. Elevated synovial white blood cell (WBC) count.

c. Elevated synovial neutrophil percentage (polymorphonuclear leukocyte % [PMN%])

d. Presence of purulence in the affected joint

e. Isolation of a microorganism in one culture of periprosthetic tissue or fluid

f. Greater than five neutrophils per high-power field in five high-power fields observed from histologic analysis of periprosthetic tissue at 400 times magnification.

In order to be included in this study, all the patients completed an informed consent form. The ethics approval was received in 2022 (no. 33/23.12.2022 issued by the Ministry of National Education-Faculty of Medicine and Pharmacy, "Dunărea de Jos" University of Galati, Romania).

The statistical analysis of the patients data was performed using the *SPSS program version 20.0* and the calculation of the chi square test, as follows: $p<0.05$, the statistical value is moderately significant (S, 95% c); $p<0.01$, the statistical value is very significant (S, 99% confidence); $p<0.001$, the statistical value is highly significant (HS, 99.9% confidence); $p> 0.05$, the statistical value is not significant (NS).

RESULTS

From a total of 4,244 patients admitted for hip arthroplasty, 76 were diagnosed with an infection associated with the surgical intervention, and from those, in 44 cases, *Stimulan* was used complementary to the classical surgical treatment.

Our study group included 31.81% women and 68.19% men. Women were older, had a bigger BMI. In their case, the infection appeared later, and the hospitalization was shorter. DAIR procedure was preferred in most women, while in the case of men, there was an equal percentage DAIR versus two-stage revision. All the characteristics of the study group are presented in the first table.

TABLE I.

Characteristics of the study group

		Total Group (n-44)	Female (n-14)	Male (n-30)	P
Age (mean ± SD) (years)		66.77±12.02	72.02±11.59	63.30±11.57	0.04
Living environment	Urban	18 (40.90%)	6 (42.85%)	12 (40%)	0.65
	Rural	26 (59.10%)	8 (57.15%)	18 (60%)	0.57
BMI		27.79±3.42	30.22±3.37	26.67±2.83	0.0007
Temperature		36.62±0.75	36.32±0.85	36.76±0.84	0.12
Time between the initial surgery and the onset of infection (days)		387 (127.5;720)	429 (150;817.5)	360 (112.5;750)	0.65
Hospitalization days		18.5 (10;46.5)	15.5 (8;48)	21.5 (10;44.25)	0.51

DAIR		25 (56.81%)	10 (71.42%)	15 (50%)	0.18
Two-stage revision		20 (45.45%)	4 (28.57%)	15 (50%)	0.38

BMI, Body Mass Index; DAIR, Debridement, antibiotics, and implant retention.

Upon admission, the most common symptoms experienced by patients were pain and functional incapacity of the lower limb. In addition, prolonged standing resulted also in discomfort/pain (fig. 1).

The main aspects of the wound are described in fig. 2.

Before surgery, WBC values varied from 2290/mm^3 to 16600/mm^3, only 40.90% of the patient having elevated levels. Only ESR and CRP were elevated in all patients at admission (fig 3).

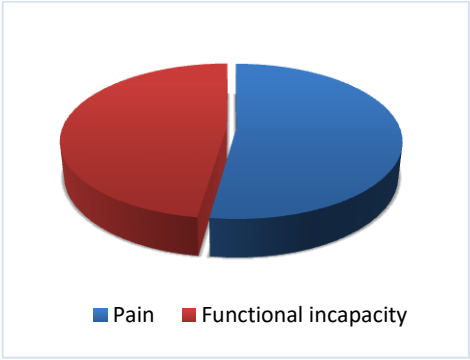

Fig. 1. Symptoms at admission

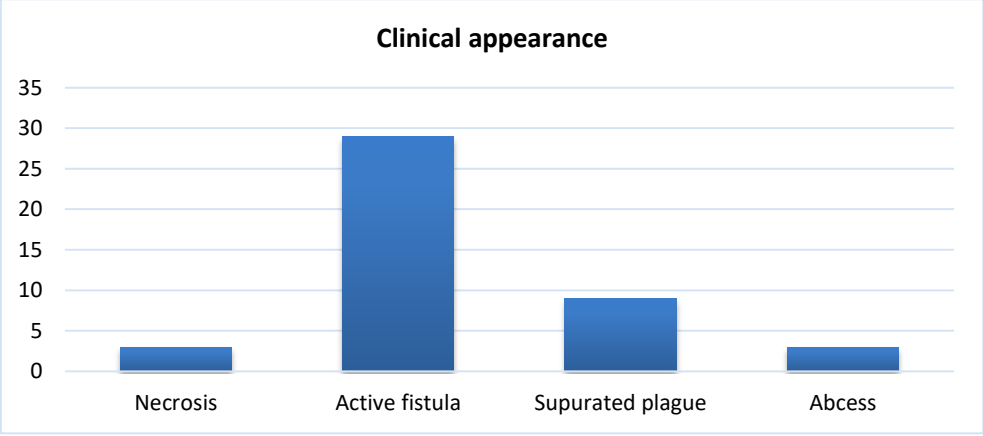

Fig. 2. Aspect of the plague

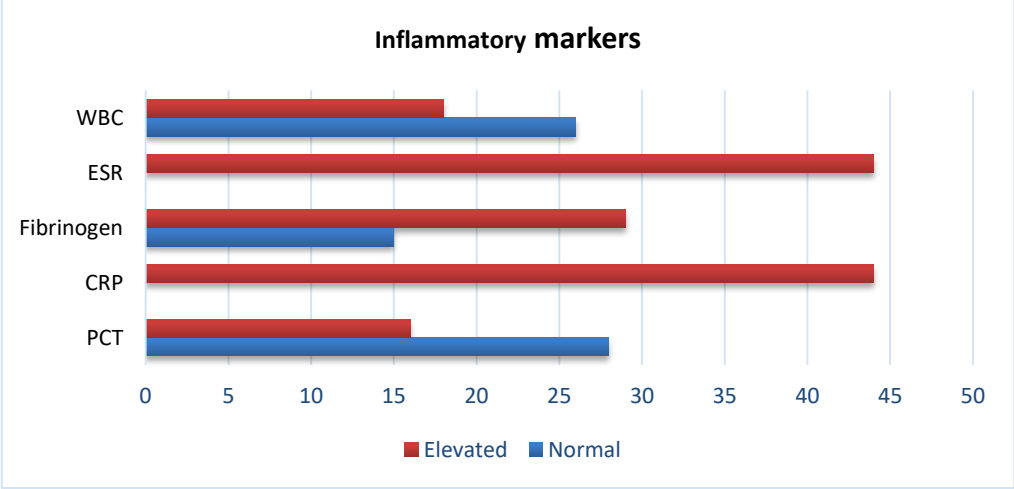

Fig. 3. Inflammatory markers upon admission

The evolution of the laboratory parameters showed a significance difference in the case of the ESR, CRP and hemoglobin (tab. II).

When we analyzed the pathogens involved in the infection, the most frequent were Methicillin-resistant Staphylococcus aureus-MSSA (34%), coagulase-negative staphylococcus-SCN-MRS (20.45%) and Methicillin-susceptible *Staphylococcus* MSS (9.09%). 4 cases had negative antibiograms (fig. 4).

TABLE II.

Evolution of the laboratory parameters

	Before intervention	2 weeks after intervention	6 weeks after intervention	P
WBC	8798 (7297;10230)	7620 (6242.25;9445)	8626 (6732;10532)	0.75
ESR	80 (61.25;120)	21.11 (15;22)	19.5 (15.25;25)	< .00001
CRP	174(147.25;223.25)	11.5 (8.07;29.25)	8.25 (4.31;9.36)	< 0.00001
Fibrinogen	455 (302.25;573)	365.5 (321.25;436.25)	321.75(257.5;385.75)	0.000043

DISCUSSION

In recent arthroplasty developments, there has been a focus on gender-specific implants for the hip and knee to account for potential anatomical differences between males and females (7). Specifically, regarding the hip, attention is given to the femoral side as there are differences in the location of the femoral head center and the shape and size of the femoral canal based on gender. Females generally have a lower offset, or a smaller femoral axis compared to male. With aging, females also tend to experience increased femoral medullary width and greater bone loss at the medial calcar and lateral cortex compared to males (8). Currently, available implant designs offer various options in stem length and diameter, neck offset, and neck length but it remains unclear whether gender makes a difference in the outcome of the patents after the hip surgery. Using nongender-specific implants, creates a difference in implant survivorship in the long-term? Are there any differences in implant-related complications?

The Swedish Total Hip Replacement Register and other large registries have demonstrated that the revision rates for hip replacements have been consistent for both men and women over the years. Additionally, the reasons for hip replacement revisions have also been similar between men and women (9).

In addition to the anatomical aspect, recent studies have begun to emphasize the psychological impact, quality of life and impact on daily activities. However, research is very limited (10).

In the present study, there are some differences between the female and male groups that are worth discussing. Women tend to undergo joint arthroplasty at an older age, possibly due to a heightened apprehension of surgery and a tendency to delay the procedure in order to minimize the impact on their caregivers' responsibilities.

BMI was higher in women, and the time interval between the first intervention and presentation to hospital for the symptoms mentioned was also longer. We have no data to confirm whether the time interval to the onset of the infectious complication was longer, or patients delayed presentation to hospital.

After the primary THA intervention, the patients declared they were called for follow-up at 14 days, at which time the sutures were removed. No intermediate follow-ups were performed until the current presentation.

At the time of the current presentation, laboratory tests and pelvis / hip X-ray were performed. In most of the cases, the X-ray did not show any specific modifications.

Detecting PJI continues to be a significant challenge for orthopedic practitioners. Research by Virolainen *et al.* (11) suggests that there is no single laboratory test currently available to accurately diagnose PJI before revision arthroplasty. Common laboratory tests such as ESR, WCC, and CRP, which are typically used as initial diagnostic tools for PJI, are not consistently reliable. Therefore, it is widely acknowledged that there is a pressing need to discover new and dependable indicators of inflammation that can facilitate the prompt and accurate diagnosis of PJI (12).

The C-reactive protein is a substance produced by the liver in response to inflammation, infection, and neoplasm. After surgery, its levels peak two to three days later and return to normal around three weeks post-surgery. Currently, most ex-

perts recommend using both the blood erythrocyte sedimentation rate and C-reactive protein level as markers for evaluating patients with a suspected prosthetic joint infection. When both markers test negative, the likelihood of infection is very low.

Following a standard joint arthroplasty, the erythrocyte sedimentation rate initially increases, peaks at five to seven days postoperatively, and then gradually returns to preoperative levels over three to twelve months.

In our study, both inflammatory markers were elevated preoperatively. Their values decreased postoperatively, and determinations at 2 and six weeks postoperatively showed normalization of ESR, while CRP remained slightly elevated. The results are different from those published in the literature, where ESR often remains slightly elevated until the end of the first year after the procedure (13), this aspect may be due both to the use of the bio composite and to the particularities of each individual patient.

In arthroplasty patients, the time taken for plasma CRP levels to return to normal after surgery has been reported as 2 (14), 3 (15) or 6-8 weeks (16), whereas White *et al.* (17) reported that, at the first follow-up visit after discharge from hospital, the CRP levels had returned to normal, although the exact time-period was not reported.

Plasma fibrinogen is a key coagulation indicator traditionally used to assess venous thrombus embolism and to regulate inflammation associated with several organ infections (18, 19). Previous research has shown that plasma fibrinogen is closely linked to the diagnosis of PJI also, with Xu *et al.* (20) being the first to show that plasma fibrinogen levels are elevated in PJI compared to aseptic failure.

The latest findings indicate that coagulation-related markers show potential for diagnosing PJI. Coagulation-related indicators offer a simple, relatively inexpensive, and noninvasive diagnostic approach compared to other tests. Additionally, coagulation function testing is a standard practice following admission. The primary function of the coagulation system is to facilitate hemostasis, and it has a close connection to infection. This system plays a role in preventing the spread of viruses through the coagulation cascade (21). Synovitis can generate significant amounts of fibrin, and the breakdown of fibrin can lead to heightened indicators with subsequent inflammatory effects (22).

The white blood cell count is a commonly used lab test that can indicate the presence of infection or inflammation. While the WBC count alone cannot definitively diagnose a specific disease, it is a valuable tool in diagnosing many diseases (23). While some studies suggest that the serum WBC count can be useful in diagnosing prosthetic joint infection (PJI), other research has conflicting findings (24, 25).

Toosi *et al.* (26) investigated the effectiveness of using white blood cell count to diagnose periprosthetic joint infection. The study revealed that the sensitivity of WBC count in diagnosing PJI was 55%, and the specificity was 66%. These findings align with the widespread opinion that serum WBC count and differential have limited utility and should not be relied upon when evaluating patients suspected of having PJI.

In our study, white blood cells were elevated in only 40% of the patients, this agrees with the results in the literature. There were no statistically significant differences between the three determinations.

The usefulness of serum procalcitonin in diagnosing periprosthetic joint infection is limited, unlike its effectiveness in detecting systemic bacterial infection. Busch *et al.* (27) conducted a study that revealed serum PCT to have low sensitivity (13%) in diagnosing PJI. Additionally, a recent meta-analysis by Yoon *et al.* (28) concluded that serum PCT plays a minimal role in the evaluation of patients with suspected PJI.

In the current study, only 16 patients showed elevated procalcitonin levels. It's important to mention that there was a consistent decrease in the levels of this marker in the postoperative follow-up assessments. The renal function remained stable, with slight postoperative increases in urea and creatinine, which later normalized.

Despite experiencing significant inflammatory symptoms, preoperative glycemic values remained below 200 mg/dL for diabetic patients and below 140 mg/dL for non-diabetic patients. These levels showed a noticeable decrease in the weeks following the surgery. Similar to other major surgeries, patients with diabetes have a higher risk of postoperative complications. Stress-induced high blood sugar is frequently seen in surgical patients and is typically caused by hormonal responses and inflammatory mediators. Elevated blood sugar levels can be due to medications, stress, poor glucose tolerance, or unmanaged diabetes. However, the patients we studied had well-managed blood sugar levels after surgery.

THA is linked to reduced hemoglobin levels, largely due to blood loss during the operation. These low Hb levels following surgery could potentially hinder the healing of surgical wounds (29-31). In our study, hemoglobin values were maintained at an average of 12.36 g/L, with a slight decrease at 6 weeks postoperatively.

PJI involves a complicated interaction between germs, mostly bacteria and sometimes fungi, and the body's immune response. Even a small number can start a PJI, as disease-causing organisms can stick to the surfaces of joint replacement components and create biofilms. The bacteria usually come from the skin's microbial community and may enter during the implantation surgery. Alternatively, these pathogens can infect the implant after surgery through the bloodstream or direct contact with nearby infected tissues (32).

Staphylococci species are the most frequent causative organisms. In our study, staphylococci account for 66% of PJI cases, confirming the previous studies' data.

The overall data of the patients included in the study seem to follow the evolution of the biological parameters of patients in previous studies, where no additional treatment (biocomposite) to the classical technique was used. The pain management and the quality of healing were important elements in the outcome analysis (33-35).

The advantages are however preserved, given the overall results and the increased cure rate.

The limitations of the study are the small number of patients, although it can be considered a positive aspect given the low infection rate.

CONCLUSSIONS

The impact of periprosthetic joint infection on patients is significant, affecting them physically, socially, and emotionally while also leading to increased healthcare costs, patient suffering, and higher mortality rates. In this study, involving 45 patients who underwent surgical reintervention and received a biocomposite following total hip

arthroplasty, the biological progression was generally typical when considering the preoperatory changes, with notable rapid improvement in inflammatory status within the first six weeks post-surgery.

However, diagnosing PJI is challenging as there is no universally accepted definition, and it can occur anywhere from 4 weeks to 2 years after the initial surgery. Additionally, the current tests used for diagnosis may only be useful in combination. The ideal scenario would be the discovery of a single biomarker with high sensitivity for accurately diagnosing PJI and relate to the evolution during the post-operative period.

CONFLICT OF INTEREST AND FUNDING

The authors declare that there is no conflict of interest, and they received no specific funding regarding this scientific research.

DRUGS REPURPOSING FOR HEART FAILURE - COMPUTATIONAL APPROACHES TARGETING SGLT2 (Abstract): Sodium-glucose co-transporter 2 (SGLT2) inhibitors are the latest approved treatment for heart failure (HF), demonstrating a significant reduction in cardiovascular outcomes associated with this condition. Based on the increasing prevalence of HF and the urgent demand for safer and more effective therapeutic options, this study employed *in silico* approaches to systematically screen a comprehensive library of conventional drugs for their binding affinity to the SGLT2 protein. **Materials and methods**: More than 70 drugs, belong to several chemical and pharmacological classes, such as proton pump inhibitors, oral hypoglycemic drugs (sulfonylureas, gliptins), statins, nonsteroidal anti-inflammatory drugs, H_1/H_2 antagonists, antineoplastic drugs, alfa-adrenergic agonists, vitamins, antioxidants, were screened for their SGLT2 affinity using molecular docking method. In addition, for the drugs with the best docking score, a pharmacokinetic profile prediction using computational tools was also performed. Canagliflozin, empagliflozin and dapagliflozin were used as SGLT2 reference inhibitors. **Results and discussion:** The docking simulations revealed that the binding of the ligands to SGLT2 involves direct hydrogen bonds and van der Waals interactions with amino acids in the active site, such as H80, G83, L84, F98, E99, V85, V157, K154, L283, V286, V287, Y290, W291 and Q457. The best docking score, much better than SGLT2 reference inhibitors, was obtained for sulfonylureas (gliquidone, glipizide, glibenclamide, glimepiride), statins (atorvastatin, simvastatin), rutin and vitamins (vitamin K and E). **Conclusions**: Based on *in silico* results, in term of affinity for SGLT2 and pharmacokinetic profile prediction, several drugs show theoretical potential for beneficial effects in HF and could be considered for further investigation in advanced studies to validate these findings. **Keywords**: IN SILICO, HEART FAILURE, SGLT2, DOCKING SCORE, PHARMAKOKINETC PREDICTORS.

INTRODUCTION

Heart failure (HF) is the primary cause of mortality worldwide, with an incidence of approximately 10 cases per 1,000 individuals aged 65 and older (1). Among those diagnosed, approximately 50% will died within five years (2). This syndrome currently affects 65 million individuals globally, and more than 15 million in Europe, and estimations for the next dec-

ades indicate a worsening situation (3, 4). It is estimated that in the US by 2030, 8 million patients will be diagnosed with HF (1).

The prevalence of HF in Western countries is estimated to range from 1% to 14%, reflecting variations in demographic factors and epidemiological trends (5, 6). Moreover, due to the aging population and modest improvements in survival after therapeutic interventions, the HF prevalence is expected to rise by up to 46% by 2030 (7). This increase will affect all age groups and will be primarily attributable to the growing prevalence of risk factors such as hypertension, diabetes mellitus, obesity, and sedentary lifestyle. In Romania, approximately 4.7% of individuals aged 35 and older are affected by HF, corresponding to an estimated 560,000 patients (8).

HF is defined as a complex clinical syndrome that arises from any structural or functional injury affecting the two primary phases of the cardiac cycle: the filling phase (diastole), during which the heart receives oxygenated blood from the lungs, and the emptying phase (systole), in which the heart contracts to pump the accumulated blood into the arteries (9).

Clinically, HF is characterized by exercise intolerance, dyspnea, edema, pulmonary hypertension, and pulmonary edema. These symptoms are primarily caused by mechanisms including cardiac hypertrophy, fibrosis, and impaired angiogenesis within the myocardium (3).

The pathophysiology of HF is driven by a complex cascade of events involving inflammatory processes and neurohormonal activation, which together contribute to cardiac remodeling, diastolic dysfunction, and impaired cardiac output. In the context of HF, systemic inflammation, hypoxia, cardiomyocyte dysfunction and apoptosis, mechanical stress, and the release of profibrotic cytokines stimulate the migration and proliferation of cardiac fibroblasts to the damaged myocardium. These fibroblasts differentiate into activated myofibroblasts which develop stress fibers, acquire enhanced contractility, and secrete profibrotic signaling molecules such as transforming growth factor beta (TGF-β), tumor necrosis factor alpha (TNF-α), and angiotensin II (7). These factors, in turn, promote cardiomyocyte hypertrophy and remodeling process, further compromising cardiac function (1).

The first-line treatment of HF therapy includes beta-adrenergic blockers, angiotensin-converting enzyme (ACE) inhibitors, mineralocorticoid receptor antagonists, and, more recently, sodium-glucose co-transporters 2 (SGLT2) inhibitors (2). Originally developed as oral anti-diabetic agents to lower blood glucose by inhibiting SGLT2 in the kidneys, SGLT2 inhibitors unexpectedly demonstrated beneficial effects on cardiovascular outcomes, both in patients with type 2 diabetes mellitus (T2DM) and in those without the condition (10). These favorable outcomes may be attributed to the pleiotropic effects of SGLT2 inhibitors on the cardiovascular system, which include blood pressure management, attenuation of inflammation, protection against cardiac remodeling, weight reduction, and preservation of kidney function (11).

SGLT2 inhibitors target the SGLT2 transporters located in S2 and S3 segments of the renal proximal tubules (and, to a lesser extent, in the small intestine), where they facilitate glucose reabsorption. By inhibiting SGLT2, these agents induce

glucosuria, natriuresis, and osmotic diuresis, leading to reductions in body weight, blood pressure, plasma volume, and both cardiac preload and afterload. Additionally, SGLT2 inhibition activates key nutrient-sensing pathways, particularly the SIRT1/PGC-1α/FGF21 axis, which in turn enhances lipolysis and ketogenesis. These hemodynamic and metabolic effects are central to the cardiovascular benefits attributed to SGLT2 inhibitors. Moreover, SGLT2 inhibitors exert direct effects on the heart by targeting the cardiac sodium-hydrogen exchanger 1 (NHE1), mitigating the detrimental consequences of elevated intracellular Na^+ and Ca^{2+} levels, and thereby alleviating mitochondrial dysfunction (10, 12).

Drug repurposing (or drug repositioning) is an emerging and promising approach in drug discovery focused on identifying novel therapeutic applications for existing, well-studied drugs. This strategy presents a valuable alternative to traditional de novo drug development, especially considering that the success rate for developing a new molecular entity is just 2%, and the number of new drug approvals has been steadily declining since the 1990s. Over the past decade, approximately one-third of drug approvals have resulted from drug repurposing (13).

In this study, a large library of conventional drugs from various chemical and pharmacological classes was screened for their affinity to the SGLT2 protein using *in silico* methods. Additionally, the pharmacokinetic profiles of the top-ranking drugs, were predicted using different descriptors such as the volume of distribution at steady state (VDss), fraction unbound to plasma proteins, blood-brain barrier (BBB) and CNS permeability.

MATERIALS AND METHODS

In silico SGLT2 docking study

Protein preparation

The 3D structure of SGLT2 protein, established using X-ray crystallography analysis, was obtained from RCSB Protein Data Bank. Prior starting the docking studies the protein structure was processed in terms of removing the ligands, the water molecules, cofactors and ions. Using AutoDock4.2.6 the protein's structure was optimized by designating bond angles, bond ordering, and topology and was stored in PDBQT format for docking (14).

Drug library preparation

For virtual screening, in terms of affinity for SGLT2, were used more than 70 drugs belong to several pharmacological classes: proton pump inhibitors, oral hypoglycemic drugs (sulfonylureas, gliptins), statins, nonsteroidal anti-inflammatory drugs, H_1/H_2 antagonists, antineoplastic drugs, alfa-adrenergic agonists, vitamins, antioxidants. The 2D structures of the used drugs were designed in ChemDraw and then converted to PDB coordinate files using Chimera 1.14. The PDB file of each drug contains special keywords such as ROOT, ENDROOT, BRANCH, and ENDBRANCH in order to be recognized by AutoDock4.2.6. The PDB file defines a fixed set of atoms and rotatable atom groups connected to the rigid base moiety. Furthermore, TORSDOF was utilized to estimate the change in free energy associated with the loss of torsional degrees of freedom upon ligand binding. Each structure underwent energy minimization before being converted into the PDBQT file format for docking (15).

Virtual screening and molecular docking

Using AutoDock-GPU software, the prepared drug library was screened against

SGLT2 using AutoDock4.2.6 scoring function, which calculate the protein-ligand binding affinity. This tool facilitates the docking of large molecular libraries and accommodates the modeling of molecules with increasing size and complexity (16). The results, represented as Gibbs free energy values (ΔG), were compared with those of currently approved SGLT2 inhibitors, including canagliflozin, empagliflozin, and dapagliflozin.

The Autogrid program was employed to generate a grid map of 65×60×60 points with a spacing of 0.375 Å between grid points and the grid box center was put on x = 38.809, y = 48.916 and z = 45.968 to calculate the ΔG for each ligand-protein complex. The binding site of SGLT2 ligands was determined through the use of protein visualization tools, including PyMOL, Chimera 1.14, and DS Visualizer. The most promising ligand-protein complexes are those with high negative ΔG value.

For virtual screening, a molecular docking file (DPF) for each ligand was generated. The DPF specifies the grid map files to be used, the ligand molecule to be docked, the docking center, the number of torsions, the docking algorithm, and the number of docking runs. The 3D ligand conformation was generated using the Lamarckian Genetic Algorithm (LGA) with the following settings: 200 runs per docking procedure, a population of 300 individuals, a maximum of 27,000 generations per LGA run, and a maximum of 25,000,000 evaluations. A mutation rate was set to 0.02, and the crossover rate to 0.80 while other docking parameters were set to their default values a. After completing the molecular docking simulations, the best ligands candidates were identified and evaluated based on their docking scores which measured the hydrophilic and lipophilic interactions between the active sites of ligand and SGLT2 protein.

The docking results were clustered using a root mean square deviation (RMSD) of 0.5 Å and analyzed using PyMol software.

Pharmacokinetics profile prediction

The pkCSM-Pharmacokinetics (http://structure.bioc.cam.ac.uk/pkcsm) and SwissADME (http://www.swissadme.ch) tools were used to predict the pharmacokinetic profile of the selected drugs (17). The pkCSM-Pharmacokinetics is a software for the prediction of small-molecule pharmacokinetic properties using graph-based signatures while SwissADME offers a comprehensive assessment of the pharmacokinetic and physicochemical properties.

RESULTS AND DISCUSION

In silico SGLT2 docking results

The PDB 7VSI file was chosen to investigate the predicted binding mode of the ligands with the SGLT2 protein. SGLT2 is characterized by the highest resolution kinase structure available to date, at 2.95 Å, which enhances confidence in the atomic positioning within the electron density map. Additionally, the reliability factor (R-value) is below 0.15, reflecting a strong agreement between the crystallographic model and the experimental X-ray diffraction data.

The computational method employed was validated by assessing the RMSD variation (less than 2 Å) for empagliflozin, based on its affinity for the active site of SGLT2, and it was found to align with the binding cleft residues reported in the literature. The docking results further indicated that the reference inhibitor, empagliflozin,

forms polar interactions with the catalytic site of SGLT2, binding deeply through specific interactions with H80, F98, and H268. Accordingly, with previous studies, key amino acids for interaction with the SGLT2 binding pocket were identified as H80, G83, L84, F98, E99, V85, V157, K154, L283, V286, V287, Y290, W291, and Q457 (14).

Each ligand (drug) - receptor complex was thoroughly analyzed to identify the optimal docked position, determined by the lowest binding energy scores and the highest number of cluster conformations. The values of the Gibbs free energies (ΔG) are presented in first table.

TABLE I.

The Gibbs free energies (ΔG) for SGLT2 of tested drugs

Ligand	SGLT-2 ΔG (kcal/mol)	Ligand	SGLT-2 ΔG (kcal/mol)
Gliquidone	-13.79	Cetirizine	-9.06
Glipizide	-12.68	Riboflavin	-8.9
Rutin	-12.52	Ketoprofen	-8.68
Glibenclamide	-12.44	Omeprazole	-8.64
Atorvastatin	-12.33	Epalrestat	-8.61
Glimepiride	-12.05	Famotidine	-8.41
Simvastatin	-11.9	Lansoprazole	-8.14
Vitamin K	-11.69	Pantoprazole	-7.93
Canagliflozin	**-11.49**	Phenytoin	-7.8
Lovastatin	-11.41	Diclofenac	-7.74
Vitamin E	-11.31	Tolrestat	-7.53
Empagliflozin	***-11.24***	Resveratrol	-7.49
Vildagliptin	-11.07	Ibuprofen	-7.22
Saxagliptin	-10.95	Antazoline	-7.21
Gliclazide	-10.75	Ranitidine	-7.18
Desmethoxycurcumin	-10.72	Nizatidine	-7.15
Dapagliflozin	***-10.69***	Tramazoline	-7.13
Alogliptin	-10.68	Naproxen	-7.03
Bisdemethoxycurcumin	-10.63	Xylometazoline	-6.98
Ezetimibe	-10.45	Oxymetazoline	-6.91
Oleanolic acid	-10.32	Cimetidine	-6.86
Rosuvastatin	-10.18	Biotin	-6.86

Ligand	SGLT-2 ΔG (kcal/mol)	Ligand	SGLT-2 ΔG (kcal/mol)
Fluvastatin	-10.09	Naphazoline	-6.85
Pravastatin	-9.97	Tacrine	-6.85
Folic acid	-9.85	Vitamin B1	-6.71
Methotrexate	-9.84	Tetryzoline	-6.68
Linagliptin	-9.74	Dexmedetomidine	-6.46
Curcumin	-9.73	Lipoic acid	-6.08
Retagliptin	-9.68	Pantothenic acid	-6.03
Pioglitazone	-9.57	Vitamin B6	-5.59
Indomethacin	-9.54	Ascorbic acid	-5.28
Sitagliptin	-9.39	Cytarabine	-5.16
Rosiglitazone	-9.34	Adenine	-4.85
Indirubin_3_monoxime	-9.15	Metformin	-4.79
Rabeprazole	-9.11	Nicotinic acid	-4.76
Indirubin-3-monoxime	-9.09	Flucytosine	-4.28

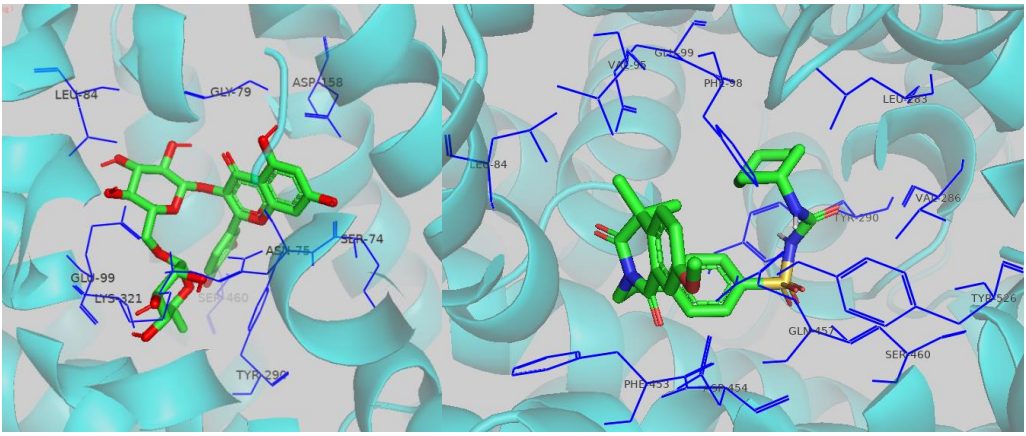
The analysis of the results showed that the estimated free binding energies (ΔG) for the reference SGLT2 inhibitors were all below -10 kcal/mol, with canagliflozin at -11.49 kcal/mol, empagliflozin at -11.24 kcal/mol, and dapagliflozin at -10.69 kcal/mol.

It is well established that ligands with the lowest docking scores require less energy to stabilize at the receptor binding site. It was observed that several drugs, belonging to different chemical structures and therapeutic classes, exhibit ΔG values lower than those of the SGLT2 reference inhibitors (canagliflozin, empagliflozin, and dapagliflozin), suggesting that these compounds have the theoretical potential to be more potent inhibitors. The most potent ligands are oral hypoglycemic drugs such as gliquidone (-13.79 kcal/mol), glipizide (-12.68 kcal/mol), glibenclamide (-12.44 kcal/mol), glimepiride (-12.5 kcal/mol), gliclazide (-10.75 kcal/mol). ΔG values less or similar to SGLT2 reference inhibitors was recorded also for rutin (-12.52 kcal/mol), statins (atorvastatin, -12.33 kcal/mol; simvastatin, -11.90 kcal/mol; lovastatin, -11.41 kcal/mol), and vitamin K (-11.69 kcal/mol).

The docking simulations revealed that the binding of the ligand to SGLT2 involves direct hydrogen bonds and van der Waals interactions with amino acids in the active site (fig. 1).

For example, rutin binds to the catalytic site of SGLT2 by forming strong hydrogen bonds with S74, N75, G79, L84, E99, Y290, and K32. Similarly, gliquidone exhibits a strong affinity for the SGLT2 active site, with hydrogen bonds formed between its sulfonylurea moiety and the amino acids Q457, S460, and Y290. Additionally, the 1,3-dioxo-2-isoquinolinyl moiety of gliquidone stabilizes the molecule through hydro-

gen bonds with Y526 and D454, as well as van der Waals interactions with amino acids from the active site, including F453, L84, F98, V95, and E99 (fig. 1).



(a) (b)

Fig. 1. The binding mode of rutin (a) and gliquidone (b) to the active site of SGLT2.

Pharmacokinetics profile prediction

The parameters related to Absorption, Distribution, Metabolism, Excretion, and Toxicity (ADME-Tox) are crucial for understanding the pharmacokinetics, pharmacodynamics, and toxicology of drugs (18, 19). These data are vital for predicting the drug's behavior *in vivo* and assessing its safety and potential adverse effects.

The drugs with the highest docking scores were selected for pharmacokinetic predictions using computational methods. The distribution properties, including the volume of distribution at steady state (VDss), the fraction unbound to plasma proteins, the blood-brain barrier (BBB) permeability and consequently the CNS permeability were predicted, and the results are presented in second table.

TABLE II.

The pharmacokinetics profile of tested drugs, predicted using pkCSM-phamacokinetics and SwissADME

Ligand	VDss (human)	Fraction unbound (human)	CNS permeability	BBB permeability
Gliquidone	-0.34	0.23	-2.74	-0.98
Glipizide	-1.29	0.00	-2.46	-0.91
Rutin	-0.25	0.25	-3.37	-1.04
Glibenclamide	-1.92	0.09	-2.92	-1.17
Atorvastatin	0.20	0.10	-2.10	-0.27
Glimepiride	-0.22	0.00	-2.68	-1.00

Ligand	VDss (human)	Fraction unbound (human)	CNS permeability	BBB permeability
Simvastatin	1.66	0.19	-5.18	-1.90
Vitamin K	0.32	0.00	-1.11	-0.29
Lovastatin	-0.44	0.00	-2.01	-0.02
Vitamin E	-0.08	0.00	-2.46	-0.34
Vildagliptin	0.09	0.25	-2.46	-0.01
Saxagliptin	-1.01	0.06	-2.20	0.25
Gliclazide	-0.67	0.19	-2.32	0.11
Demethoxycurcumin	-1.64	0.08	-2.03	-0.57
Alogliptin	0.59	0.57	-3.13	-0.66
Bisdemethoxycurcumin	0.28	0.25	-2.62	-0.29
Ezetimibe	0.27	0.24	-2.96	-1.51
Oleanolic acid	-1.01	0.00	-1.18	-0.14

It is well established that only the unbound fraction of a drug is pharmacologically active, while high protein binding can influence both the pharmacokinetic and pharmacodynamic profiles of drugs (19).

The analysis of the results showed that the values of fraction unbound ranged from 0 (glipizide, glimepiride, vitamin K, vitamin E, lovastatin, oleanolic acid) to 0.57 (alogliptin). For VDss, the values recorded ranged from -1.92 (glibenclamide) to 1.66 (simvastatin).

To determine the statistical significance of the difference between VDss and the fraction unbound, while accounting for ligand variances in the overall error variance, a two-way ANOVA analysis was conducted. The results indicated no statistically significant difference between the two parameters ($F(0.5, 1, 16) = 11.302$, $p = 0.001$, $Fcrit = 4.358$). Thus, the lower VDss values correlate with a lower fraction of drug molecules in the plasma that are unbound (free) to proteins.

The BBB permeability is evaluated using two parameters: a qualitative measure (BBB) and a quantitative one (logBB). A value of logBB higher than 0.3 suggests that the drug crosses the BBB, having a high permeability, while a value less than -1 indicates a limited BBB permeability (19). For the tested drugs the BBB permeability values ranged between -1.90 (simvastatin) to 0.25 (saxagliptin), that means that could be classified as drugs with poor distribution to brain.

The drugs with the best pharmacokinetic predictors, in term of VDss (less than 0.5) and BBB permeability (less than -1), were oral the hypoglycemic drugs, such as glipizide (VDss = -1.29, BBB = -0.91,) glibenclamide (VDss = -1.92, BBB = -1.17) and gliclazide (VDss = -0.67, BBB = 0.11). Appropriate values were also recorded for: rutin (VDss = -0.25, BBB = -1.04), demethoxycurcumin (VDss = -1.64, BBB = -

0.57); vildagliptin (VDss = -0.09, BBB = 0.01); vitamin E (VDss = -0.08, BBB = -0.34) and vitamin K (VDss = 0.32, BBB = -0.29). The values recorded for canagliflozin, empagliflozin and dapagliflozin, used as SGLT2 references inhibitors, were VDss = -0.71, BBB = -0.99 (canagliflozin); VDss = -0.39, BBB = -1.10 (empagliflozin) and VDss = 0.33, BBB = -0.99 (dapagliflozin), respectively.

CONCLUSIONS

Drug repurposing is an emerging and promising strategy in the medical and pharmaceutical fields, focusing on discovering new therapeutic uses for drugs that have already been approved for other conditions. This approach offers a valuable alternative to traditional de novo drug development, as it is faster and more cost-effective.

Using AutoDock-GPU software, a large drug library was screened against SGLT2 using AutoDock4.2.6 scoring function, which calculate the protein-ligand binding affinity. The most promising drugs that showed SGLT2 binding affinity much better than known SGLT2 inhibitors (canagliflozin, empagliflozin, dapagliflozin) are sulfonylureas (gliquidone, glipizide, glibenclamide, glimepiride), statins (atorvastatin, simvastatin), rutin and vitamins (vitamin K and E). These drugs showed also a good pharmacokinetic profile, having a poorly blood brain barrier permeability (BBB less than −1) and a proper volume of distribution at steady state (VDss less than 0.5). Based on *in silico* results, the most favorable drugs will be considered for further investigations using *in vitro* and *in vivo* assays

CUT-OFF VALUES OF BODY FAT PERCENTAGE AND INSULIN FOR PREDICTING LOW ADIPONECTIN / LEPTIN RATIO (Abstract): This study **aims** to establish a reliable parameter and its optimal cut-off point for accurately estimating adipose tissue dysfunctionality in apparently healthy, but abdominally obese subjects. **Materials and methods:** The 104 subjects included in the study, all with no prior chronic diseases, underwent biochemical (TG, HDL-c, glucose, insulin, adiponectin, leptin) and anthropometric measurements (waist circumference, height, adipose tissue percentage). A ROC curve was performed to assess the overall performance of these parameters to determine the dysfunctionality of the adipocytes, as assessed by adiponectin: leptin ratio (ALR) lower than 0.5. Logistic regression identified models that included 2 or 3 parameters to further increase the accuracy. The software Excel and SPSS were used for the statistical analysis. **Results:** From all individual parameters, trunk adipose tissue percentage had an AUC value of 0.812, suggesting a high accuracy for predicting a value of ALR<0.5. The optimal cut-off point for trunk adipose tissue percentage was established at 42.45% with a sensitivity of 0.725 and a specificity of 0.766. A higher AUC (0.857) was observed for the model that included whole-body adipose tissue (cut-off 41.7%) and insulin (cut-off 14.6 μU/mL), while the highest accuracy (AUC=0.889) was reported in the model for metabolically unhealthy non-obese subjects. **Conclusions:** Apparently healthy individuals, but abdominally obese, report adipocyte dysfunctionality together with high cardiometabolic risk at values for trunk adipose tissue percentage surpassing 42.45%, or combined values of 41.7% for whole-body adipose tissue and 14.6 μU/mL for insulin. **Keywords:** CUT-OFF VALUES, BODY FAT, INSULIN, ADIPONECTIN / LEPTIN RATIO.

INTRODUCTION

It is well-established that quantity and quality of adipose tissue play a critical role in metabolic health, as both excessive or insufficient adipose tissue are associated with significant health risks. In conditions such as congenital or acquired lipoatrophy insufficient adipose tissue leads to severe metabolic disturbances and conversely, obesity is also linked to similar metabolic complications (1, 2). Adipocytes have a unique secretory profile that includes adipokines like leptin and adiponectin, cytokines or various metabolites, which collectively interact to establish communication pathways between organs (3). Their bal-

ance is vital for organism physiology, therefore accurately identifying adiposopathy is pivotal in a clinical setting for prevention and diagnostics strategies, while particularly challenging to attain. Previous studies have confirmed adiponectin/leptin ratio, as opposed to single biomarker approaches, as a diagnostics tool for adipocyte metabolism dysfunctionality, with lower values than 1 being associated with cardiometabolic risk (4, 5).

This study aims to establish a reliable parameter and its optimal cut-off point for accurately estimating adipose tissue dysfunctionality defined as adiponectin/leptin ratio < 0.5. There are some key points we consider as arguments for this analysis. While adiponectin and leptin together profile the status of adiposopathy and that of cardiometabolic risk, these assays are not performed usually as screening tests in individuals and their cost is handled by the patient, therefore a balanced solution would be highly valued. Judging from an economical and practical point of view, the detailed profile of an individual that represents the core of personalized medicine is still hard to portray. However, modern technologies including artificial intelligence or advanced statistics aid in generating a more complete profile as possible. To generate algorithms solely for adiponectin and leptin with the help of hands-on and easy to obtain parameters is a challenging task. Therefore, our study focused on predicting the reduced ratio levels between the two which has a broader significance and could tell us more about the functionality of the adipose tissue, despite its limited focus on specific outcomes. We expect to have a more detailed picture of the apparently healthy individual that also has abdominal obesity, with respect to adipocyte metabolism and cardiometabolic implications.

MATERIALS AND METHODS

This observational cross-sectional study included 104 subjects, aged 35-75 years old (25.96% men and 74.04% women), with abdominal obesity and no prior known chronic disorders or acute atherosclerotic events in antecedents. All patients underwent biochemical and anthropometric measurements in the morning, with blood samples being collected after a 12 hrs. overnight fast. Serum samples for marker analysis were stored at -20ºC. Glucose, TG, HDL-c levels were determined using the spectrophotometric method, insulin using chemiluminescence, adiponectin and leptin with ELISA technique.

Visceral adiposity index was calculated based on previous validated equations (6). For adipose tissue mass and percentage, dual-energy X-ray absorptiometry (DEXA) was used, as a gold standard for this measurement.

The population included in the cohort was apparently healthy, but after investigations some subjects presented metabolic syndrome (MetS). The presence of MetS included waist circumference > 88 cm (women)/104 cm (men) and at least 2 of the following criteria: glucose ≥ 100 mg/dL, HDL < 40 mg/dL (men) / < 50 mg/dL (women), TG ≥ 150 mg/dL, SBP/DBP ≥ 130/85 mmHg (7).

Data was processed with Excel and SPSS. Distribution was assessed for all variables with the Kolmogorov-Smirnov test and confirmed visually, analyzing the histograms. Correlations between variables were performed with Spearman and Kendall's tau-b test. Logistic regression delivered models with high performance and the predicted probability calculated for these models was further used as input for the

receiver operating characteristic (ROC) curve for determining specific biomarker values to better predict a low ALR.

RESULTS

All analyzed variables are non-normally distributed, except trunk adipose tissue percentage which has a normal distribution. In this study 74.04% of the subjects were women and 25.96% were men, with a mean age of 59.51±8.18. Baseline characteristics of the study are presented in first table.

TABLE I.
Baseline characteristics of the study group

Parameter	Median (Q3-Q1)	Min	Max
Age (years)	62 (53-65)	39	75
BMI (kg/m^2)	30.99 (28.57-34.39)	21.91	53.31
BMI (kg/m^2) - women	30.23 (28.01-34.23)	21.91	49.50
BMI (kg/m^2) - men	32.43 (30.17-35.61)	22.75	53.31
Waist circumference (cm)	106 (99-115)	89	160
Insulin (µU/mL)	15 (9.38-21.45)	2.13	52
Glucose (mg/dL)	103 (94-116)	76	336
HOMA-IR	3.78 (2.38-5.99)	0.49	27.25
Adiponectin (µU/mL)	13.02 (10.33-16.77)	4.53	28.53
Leptin (ng/mL)	19.63 (11.22-39.67)	2.60	58.20
ALR	0.59 (0.33-1.36)	0.13	4.98
eVAI	4.50 (3.15-7.64)	1.38	33.66
Whole-body adipose tissue (%)	41.10 (36.32-44.27)	18.90	53.20
Parameter	**Mean±S.D.**	**C.I. (95%)**	
		Lower limit	**Upper limit**
Trunk adipose tissue (%)	40.30 ± 6.42	39.05	41.55

* S.D.= standard deviation, Q3-Q1=difference between superior quartile and inferior quartile, ALR=adiponectin/leptin ratio, eVAI=estimated visceral adipose index.

The correlation matrix between biomarkers and parametric variables describing adipose tissue health report ALR as having stronger correlations with obesity parameters than adipokines alone. The eVAI parameter reports little to no correlation with all the other variables, adipose tissue percentage presents a stronger correlation with ALR than BMI and insulin is stronger correlated with ALR than HOMA-IR. All correlation coefficients over 0.200 are statistically significant (tab. II).

Logistic regression rendered two best models presented in third table for estimating the status of ALR < 0.5. Variables with the strongest correlation were the ones that performed best, with whole-body adipose tissue percentage and insulin being the most important influencers for low ALR. In order to calculate the accuracy of each parameter and model for assessing low ALR, ROC curve analysis was performed (fig. 1).

The AUC values of factors predicting adipose tissue dysfunctionality confirms high accuracy for adipose tissue percentage, insulin and the 2 models (tab. IV). Optimal cut-off points were chosen for these parameters, preserving in the same time the highest sensitivity and specificity possible (tab. V).

DISCUSSION

In the present study we identified predictive values of biomarkers and representative parameters of body composition for adipose tissue dysfunctionality. The main finding is that adipose tissue percent-

age together with insulin identify the presence of ALR lower than 0.5 with a high accuracy rate. The optimal cut-off point for trunk adipose tissue percentage is 42.45% and for insulin is 14.9 μU/mL. These values are referenced against other established thresholds for cardiometabolic risk in several studies. Bawasi H. *et al*. proposed sex-specific cut-off points for adipose tissue percentage in people over 40 years old, with values of 34.8% (men) and 46.3% (women) for total adipose tissue or 21.6% (men) and 23.4% (women) for trunk adipose tissue (8). The collaborative group of Macek P. reports optimal cut-off points for body fat percentage of 25.8% for men and 37.1% for women (9). These values are not standardized as they reflect a threshold for cardiovascular risk that is measured distinctly for every study, therefore it remains difficult to compare them between each other. Furthermore, to the best of our knowledge, this is the first study that calculates a cut-off point of body fat percentage for determining adiposopathy defined as low ALR and moreover, it predicts severe cardiometabolic risks since the value presents an important decrease (inferior to 0.5).

A recent comprehensive review emphasizes that besides BMI, more essential to measuring the extent of adiposity are waist circumference and body fat percentage. Together with the clinical component these are critical for a complications-centric approach to obesity care, which aligns with the Adiposity-Based Chronic Disease framework (10). A position statement on visceral and ectopic fat highlights the necessity of creating and implementing methods to detect individuals with excessive adiposity, both in clinical settings and within public health initiatives (11). Moreover, trunk adipose tissue percentage, particularly visceral fat is strongly associated with metabolic risk factors, including insulin resistance, reinforcing the utility of adipose tissue percentage as a reliable predictive marker (12), together with adiponectin and leptin as primarily derived molecules from adipose tissue (13) as promising candidates for distinguishing between insulin-sensitive and insulin-resistance obesity phenotypes (14).

The variables included in the models were depicted based on their influence on adiponectin-leptin ratio, which was assessed with logistic regression. Even though the clinical obesity phenotype variable does not have a significant p value as a whole group, model 2 outperformed model 1. Insulin is present in both models in our study, confirming its key influence on ALR, since insulin resistance likely results from the dynamic interrelationship between multiple adipokines rather than the action of a single molecule. Important pathophysiological processes take place when leptin is hyper secreted and adiponectin underproduced, like: pancreatic β-cells damage reducing insulin production, exacerbation of glucose intolerance (15), suppression of glucose transporter-4 and insulin receptor substrate-1 expression (16, 17). In our study HOMA-IR reported a lower accuracy rate for predicting adipose dysfunctionality than insulin alone, however the values demonstrated proximity. To confirm whether indeed insulin or HOMA-IR is more relevant in a clinical setting to predict adipose dysfunctionality, we would need to extend the study to a larger cohort.

The ROC analysis used in our study depicts the trade-off between sensitivity and specificity over a series of established thresholds for different obesity linked pa-

rameters. The optimal cut-off points were chosen based on the Younden index, the global measure of biomarker effectiveness (18). However, the choice could be subjective depending on the severity of the disease. In our case, identifying adiposopathy is mostly used in preventive or cardiovascular stratifying programs, therefore we can accept a balance between correctly and incorrectly classifying individuals with the disease. In severe pathologies, we would need to choose a cut-off point that provides 100% sensitivity, even if the specificity in this case would be low.

Since it is difficult in clinical settings to find the specific values for all variables in one patient, these models are difficult to implement in a day by day practice. Therefore, individual variables could be of better use to clinicians, since they provide a clear percentage of false positives or false negatives regarding adiposopathy. Since body composition analysis implies a high cost, artificial intelligence networks can be used to calculate adipose tissue percentages with high accuracy, therefore making it almost cost-free to estimate ALR. The limitation is, of course, the false positive and false negative rates that have to be considered. Our group worked on an algorithm that predicts with high accuracy trunk adipose tissue mass from easy to measure anthropometric parameters (19), while there are also other models performed on larger cohorts sustaining the need for this cost-effective prediction tool (20-22).

CONCLUSIONS

Apparently healthy individuals, but abdominally obese, report adipocyte dysfunctionality together with high cardiometabolic risk at values for trunk adipose tissue percentage surpassing 42.45%, or combined values of 41.7% for whole-body adipose tissue and 14.6 μU/mL for insulin. Adipose tissue percentages can be easily and accurately estimated based on already developed algorithms, therefore the severe cardiometabolic risk linked to ALR values lower than 0.5 can be estimated almost cost-free.

These findings have clinical relevance for patient care and contribute significantly to the advancement of personalized medicine, particularly within the context of preventive strategies and cardiovascular risk stratification.

EVALUATION OF ANXIETY FOR FIRST AND SECOND TRIMESTER PREGNANT WOMEN INFECTED WITH COVID-19. A CLINICAL STUDY (Abstract) **Aims:** During the COVID-19 epidemic, a widespread worsening in mental health was recorded. This study aimed to assess the psychological impact on mothers and to quantify the percentage of Romanian women infected with SARS-CoV-2 during the first and second trimesters of pregnancy who exhibited clinically significant anxiety symptoms (GAD-7 score > 10) and their associated concerns. **Materials and methods:** Between July 1st, 2021, and March 31st, 2022, 45 patients with a confirmed mild or moderate SARS-CoV-2 infection and a pregnancy less than 24 weeks of gestation were admitted to the 2nd Clinic of Obstetrics and Gynecology at the "Sf. Apostol Andrei" Clinical Emergency County Hospital Galați for treatment and investigations. Data collection was accomplished through the development of a questionnaire that comprised fourteen items. The clinical data and GAD-7 anxiety score were subsequently analyzed. **Results:** For 23 patients (51.11%), the GAD-7 score ranged from 0 to 4, indicating low anxiety. Conversely, in 4 patients (8.88%), the GAD-7 score ranged from 10 to 14, indicating moderate anxiety, while in 3 cases (6.66%), the GAD-7 score was 15, indicative of severe anxiety. **Conclusions:** Despite the large amount of literature on anxiety-depressive disorders during pregnancy, especially in the third trimester and postpartum, there is a lack of studies focusing on the mental health of pregnant women diagnosed with SARS-CoV-2 infection, particularly in the first trimester. This is especially significant considering the limited understanding of the relationship between the adverse effects of viral infection on pregnancy and maternal-fetal outcomes. **Keywords:** PREGNANCY, COVID-19, MENTAL HEALTH, GAD-7.

INTRODUCTION

In March 2020, the World Health Organization (WHO) designated COVID-19 (Coronavirus Disease 2019) as a global pandemic. Over the past five years, the pandemic has presented myriad obstacles to individuals around. Throughout the pandemic, various waves emerged, marked by intervals of rising COVID-19 cases. To mitigate the influx of new infections, numerous countries implemented social restrictions and lockdowns (1). The SARS-CoV-2 pandemic has impacted the worldwide economy, national infrastructures, healthcare systems, and the overall welfare of the global population. The Romanian authorities have adjusted to the pandemic, implementing several steps to safeguard public health (2).

The pandemic has been especially frightening for pregnant women. The majority of pregnant women infected with SARS-CoV-2 exhibit either asymptomatic or moderate symptoms (3). They frequently manifest with fever and cough, and less commonly with myalgia and chills.

The most often documented unfavorable outcomes in pregnant women with SARS-CoV-2 infection were preterm delivery and low birth weight (4). Additional obstetric consequences including stillbirth, miscarriage, preeclampsia-like syndrome, fetal growth restriction, coagulopathy, premature rupture of membranes, and postpartum hemorrhage, all of which remained infrequent (4-6).

During the COVID-19 pandemic, it was reported a general decline in mental health; however, women exhibited a 44-75% greater rise in adverse mental health outcomes compared to men (7). Fluctuations in mental health are frequently ascribed to significant life alterations, such as the implementation of remote work regulations and job loss, occurrences that may lead to heightened substance use and elevated suicide rates (7, 8). Given the impact of COVID-19 on mental health in the general population, it is highly probable that pregnant women experienced analogous elevations in the risks for mental health and substance use disorders.

In 2006, Spitzer introduced the 7-item Generalized Anxiety Disorder scale (GAD-7) as a brief measure for assessing anxiety disorders (9). Only in 2014, the National Institute for Health and Care Excellence (NICE) suggested the GAD-7 as a screening tool for identifying anxiety during routine mental health assessments in antenatal as well as in postnatal period (10). Nonetheless, the NICE requested more validation of GAD-7 within the pregnant population. This advice was mostly based on expert consensus rather than the quantity of studies (11).

Although there are numerous reports in the literature on anxiety-depressive disorders throughout pregnancy, particularly in the third trimester and postpartum, there are very few studies addressing mental health in pregnant women who have been diagnosed with Sars-Cov-2 infection, particularly in the first trimester. This is especially relevant given that little was known about the association between the detrimental impact of viral infection on pregnancy and maternal-fetal outcome.

MATERIALS AND METHODS

The aim of this study was to evaluate maternal psychological impact and to determine the proportion of women with clinically significant symptoms of anxiety (GAD-7 $\geq$ 10) among Romanian women who were infected with SARS-CoV-2 dur-

ing first and second trimester of pregnancy and their concerns.

A number of 45 patients with pregnancy less than 24 weeks of gestation, with confirmed mild or moderate SARS-CoV-2 infection (SpO2 ≥ 94% and clinical evidence of lower respiratory tract disease), were addressed and admitted to 2nd Clinic of Obstetrics and Gynecology, Clinical Emergency County Hospital" Sf. Apostol Andrei" Galați for investigations and treatment during July 1st 2021 and March 31st 2022. Pulmonary CT was not performed in our case series due to specific contraindications in pregnancy as well as the fact that none of the patients was in a severe clinical condition.

The GAD-7 questionnaire (fig. 1) was translated and used for data collection. Patients were asked to participate in the study and fill in the questionnaire at the first consultation / admission to the hospital. Clinical data along with GAD-7 anxiety score were then analyzed.

GAD-7 Anxiety

Over the last two weeks, how often have you been bothered by the following problems?	Not at all	Several days	More than half the days	Nearly every day
1. Feeling nervous, anxious, or on edge	0	1	2	3
2. Not being able to stop or control worrying	0	1	2	3
3. Worrying too much about different things	0	1	2	3
4. Trouble relaxing	0	1	2	3
5. Being so restless that it is hard to sit still	0	1	2	3
6. Becoming easily annoyed or irritable	0	1	2	3
7. Feeling afraid, as if something awful might happen	0	1	2	3

Fig. 1. GAD-7 Anxiety score

The study was approved by the institutional ethics committee (No. 12534/2021), and complied with the Declaration of Helsinki. Written consent was obtained from all patients included in this study.

RESULTS

The data obtained from the study questionnaire is systematically presented first table. In all 45 cases, age varied between 19 and 42, with a mean of 28.5 ± 5.98 years, and the antigen test for SARS-CoV-2 was positive. All cases were first or second trimester pregnant women. In most cases, the pregnancy was below 12 weeks of gestation (23 patients, 51.11%). In 7 cases (15.55%) the pregnancy was between 20 and 24 weeks of gestation.

Although respiratory symptoms were mild or moderate, other obstetric manifestations were noted. Uterine contractions, resembled by patients as lower hypogastric colicky pain, were identified in 35 cases (77.77%), whereas hyperemesis was encountered in 11 cases (24.44%). In 5 cases (11.11%) genital or urinary tract infections were also present.

TABLE I.

Clinical and demographic features of the cases

Age (years): < 20 20 - 29 30 - 39 > 40	19 - 42 years, 28.5 ± 5.98 (mean ± SD) 4 (8.88%) 19 (42.22%) 21 (46.66%) 1 (2.22%)
Region	Urban: 30 (66.66%) Rural: 15 (33.33%)
Education	Primary school: 1 (2.22%) Secondary school: 4 (8.88%) High school: 29 (64.44%) University: 11 (24.44%)
Marital status	Yes: 35 (77.77%) No: 10 (22.22%)
Smoking	Yes: 12 (26.66%) No: 33 (73.33%)
Parity *	0: 30 (66.66%) 1 - 3: 14 (31.11%) > 4: 1 (2.22%)
Time from the last delivery: (parity ≠ 0)	< 2 years: 0 > 2 years: 15 (100%)
Breastfeeding (duration if any): (parity ≠ 0)	0 months: 1 (6.66%) < 6 months: 1 (6.66%) 6 - 12 months: 8 (53.33%) > 12 months: 5 (33.33%)
Abortions	0: 26 (57.77%) 1 - 3: 18 (40%) > 4: 1 (2.22%)
Gestational age (weeks)	< 12: 23 (51.11%) 12 - 15: 10 (22.22%) 16 - 19: 5 (11.11%) 20 - 24: 7 (15.55%)
Symptoms	Uterine contractions: 35 (77.77%) Hyperemesis: 11 (24.44%) Uterine/genital infection: 5 (11.11%)
SARS-CoV-2 Ag positive	45 (100%)
COVID-19 vaccination	Complete: 32 (71.11%) Incomplete: 5 (11.11%) No: 8 (17.77%)
GAD-7 score	5.08 ± 4.24 (mean GAD-7 score ± SD) 0 - 4 (minimal anxiety): 23 (51.11%) 5 - 9 (mild anxiety): 15 (33.33%) 10 - 14 (moderate anxiety): 4 (8.88%) > 15 (severe anxiety): 3 (6.66%)

Values are expressed as absolute numbers, percentages, mean ± SD

* Parity is defined as the number of times a woman has given birth to a live neonate, at 24 weeks or more, regardless of whether the child was viable or non-viable.

Analyzing the demographic features of the cases, we found that most of the patients were from urban regions (30 cases, 66.66%), married (35 cases, 77.77%) and with secondary and higher education status (high school - 29 cases, and university degree - 11 cases).

In terms of COVID-19 vaccination, 32 cases (71.11%) had completed the immunization schedule regardless of vaccine manufacturer. Just 8 cases (17.77%) had no COVID-19 vaccination at all.

All cases agreed and completed the GAD-7 questionnaire. Mean GAD-7 score was 5.08 with a standard deviation of 4.24 with values between 0 and 15, presented in histogram (fig. 2). In 23 patients (51.11%), the GAD-7 score was between 0 and 4 which stands for minimal anxiety. In contrast, in 4 patients (8.88%) the GAD-7 score was between 10 and 14 suggestive for moderate anxiety, whereas in 3 cases (6.66%) the GAD-7 score was 15, suggestive for severe anxiety.

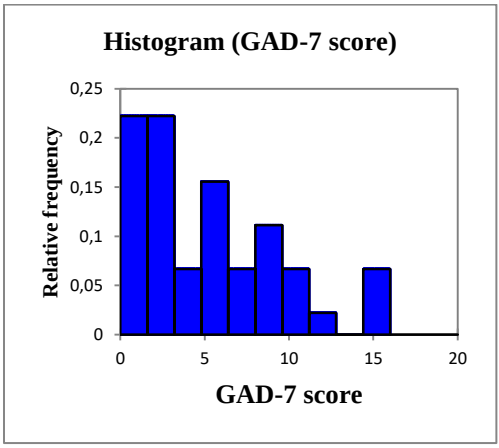

Fig. 2. GAD-7 score histogram for all patients included in the study

Analyzing the GAD-7 score in respect with the age of the patients, the correlation was only moderate (r = 0.415; p < 0,001) (fig. 3).

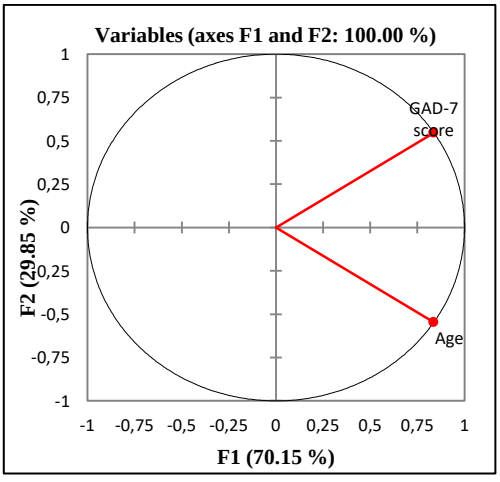

Fig. 3. Correlation between GAD-7 score and age of the patients (r = 0.415; p < 0.001)

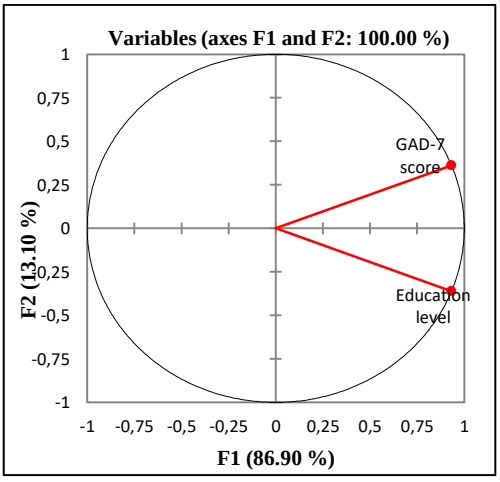

Fig. 4. Correlation between GAD-7 score (≥ 10) and level of education (r = 0.757; p < 0.001)

Pearson correlation between patients with moderate and severe anxiety (GAD-7 score ≥ 10), and the level of education showed a strong association (r = 0.757; p < 0.001) (fig. 4). In contrast, the correlation between GAD-7 score below 10 and the

educational level was not statistically significant.

Furthermore, a strong correlation was found between GAD-7 score and parity (r = 0.788; p < 0.001) (fig. 5), where an association was found between higher scores and lower parity. A strong correlation was also found between GAD-7 score and gestational age (r = 0.922; p < 0.001) (fig. 6), where an association was found between higher GAD-7 score and higher gestational age. Patients with complete immunization for COVID-19 had lower GAD-7 scores. In this respect, a strong correlation between GAD-7 score and vaccination status was noticed (r = 0.680; p < 0.001) (fig. 7).

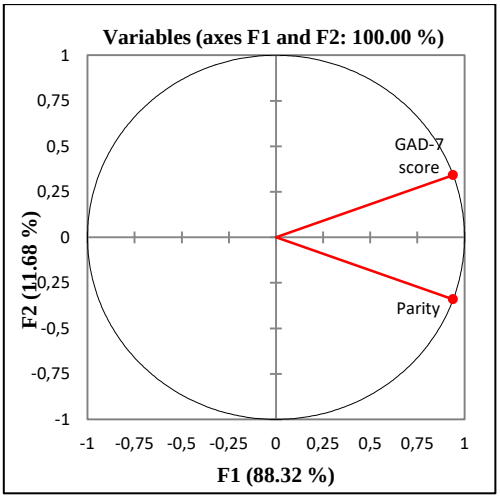

Fig. 5. Correlation between GAD-7 score and parity (r = 0.788; p < 0.001**)**

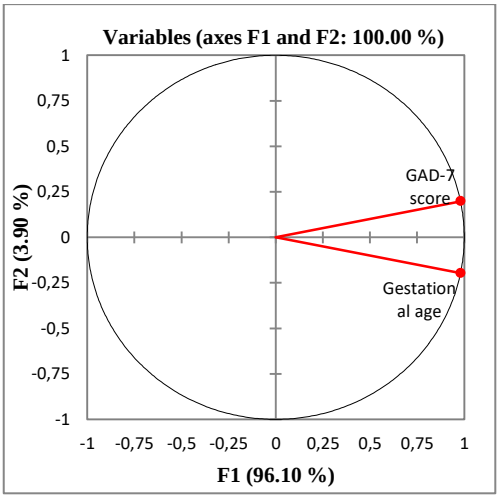

Fig. 6. Correlation between GAD-7 score and gestational age (r = 0.922; p < 0.001)

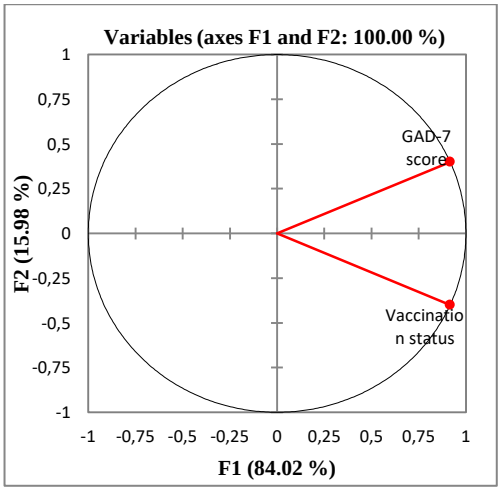

Fig. 7. Correlation between GAD-7 score and COVID-19 vaccination status (r = 0.680; p < 0.001)

DISCUSSION

Pregnancy is a phase of significant and rapid physiological transformation, during which the likelihood and repercussions of mental health disorders are heightened. Pregnant women face an increased risk of developing psychiatric disorders compared to nonpregnant women, which may continue after pregnancy ends (12, 13). Symptoms of anxiety or depression occur in 30%-58% of pregnancies, while phobias, mania, and obsessive-compulsive disorders are recorded at lesser rates (12, 13).

Anxiety is among the most prevalent psychiatric disorders during pregnancy. As many as 25% of women receive anxiety-

related diagnoses during pregnancy, with an additional 20% experiencing anxiety in the postpartum period (14). Anxiety may emerge from maternal apprehensions, such as the timing of labor, previous adverse experiences within the hospital and the health of the infant (13). Anxiety during pregnancy is frequently linked to exhaustion, physiological alterations resulting from pregnancy, and mood fluctuations that may encompass depressive symptoms (15).

Depression is a prevalent psychiatric disorder, affecting 10%-40% of women during pregnancy. Pregnant women experiencing anxiety or depression may have an elevated risk of preterm birth, cesarean delivery, and postpartum depression (PPD) (14, 16, 17). PPD is defined by depressive symptoms accompanied by anxiety, heightened arousal, and mood lability (16, 17). This issue impacts as many as 19% of mothers from 2 weeks to 1.5 years after delivery (16, 17). Moreover, postpartum depression (PPD) frequently coexists with other postpartum mental health disorders, such as anxiety disorders, and is linked to a heightened risk of obsessive-compulsive disorder or harmful thoughts towards one's newborn (13, 18).

Recent studies demonstrate that pregnant women with mental health disorders are at an increased risk of adverse pregnancy outcomes. Mental health disorders in pregnant women may elevate the risk of unfavorable outcomes, including hypertension throughout pregnancy, delivery issues, and an increased risk of alcohol consumption, recreational drug use, and smoking as coping strategies (13, 19). Poor maternal mental health in newborns may lead to consequences including preterm birth, low birth weight, and impaired cognitive and language development (20). Mental health issues in pregnant women influence not only their own health outcomes but also have a transgenerational effect on their infants.

In addition, the degree of maternal illness correlated with an increased chance of cesarean section, premature delivery, and the necessity for neonatal intensive care unit admission.

Ma and colleagues (21) performed a meta-analysis involving 19,884 subjects diagnosed with COVID-19. The aggregated percentage of asymptomatic infections was 54.1% in pregnant women, in contrast to 40.5% in the general population. Vouga and colleagues (22) documented a 9.9% incidence of severe COVID-19 in a group of 926 pregnant women who tested positive for SARS-CoV-2. In these pregnant women, the risk factors for severe COVID-19 were pulmonary comorbidities, hypertension, and diabetes. Pregnant women with symptomatic COVID-19 exhibited a higher likelihood of hospitalization (RR 5.4), immunosuppression with bacterial sepsis (23), admission to intensive care units (RR 1.5), intubation and mechanical ventilation (RR 1.7), and mortality (24). Maternal mortality from all causes was 11.3% among pregnant women, in contrast to 6.4% for non-pregnant hospitalized women (25).

Recent studies have indicated a heightened incidence of anxiety and depression among pregnant women following the commencement of the COVID-19 pandemic relative to pre-pandemic levels (26). Throughout this period, pregnant women often expressed health care concerns, including difficulties in accessing hospital services, inadequate support from partners

and family during childbirth, anxiety about transmitting COVID-19 to their fetuses or newborns, and apprehension that maternal COVID-19 infection could result in developmental defects or delays in their children (26). These concerns were also highlighted by our study revealing that higher anxiety scores were more frequently associated with low parity, higher educational level and higher gestational age. The pressures of the pandemic may have significantly impacted maternal mental health, consequently influencing the overall health of both mother and child.

GAD-7 scale is selected as a screening instrument for prenatal anxiety for several reasons. It is widely recognized that pregnant women typically encounter many somatic complaints, including fluctuations in weight and sleep disturbances. On the other hand, the GAD-7 contains limited measures that evaluate somatic symptoms, so mitigating the potential misinterpretation that these symptoms may stem from typical pregnancy experiences rather than psychological disorders (27).

The creation of COVID-19 vaccinations was deemed crucial for decreasing COVID-19-related morbidity and mortality in the general population, including pregnant women (28). The Romanian authorities advised vaccination during any trimester of pregnancy and during the breastfeeding phase as well. However, the recommendation of the COVID-19 vaccine among pregnant women was an additional source of worry and generally hardly accepted due to insufficient data on safety and efficacy, coupled with the proliferation of misinformation on social media regarding the vaccine's teratogenicity (29). Surpassing all the questions and misinformation about COVID-19 vaccine, as in our study and others from the literature, immunization against SARS-CoV-2 offered a better confidence and a lower level of anxiety in pregnant women compared with women who received no vaccination at all (30, 31).

CONCLUSIONS

The global COVID-19 pandemics was a milestone in humankind medical care. Pregnant women faced a lot of challenges and uncertainties. Social distancing, reductions in prenatal visits, lack of access in many medical facilities along with insufficient knowledge about the infection itself, the consequences on both mother and fetus, the overall prognosis, the short- and long-term effects of vaccines have created the foundation of worries, anxiety and depression. Although diagnosed more often during third trimester and postpartum period, SARS-CoV-2 infection in pregnant women led to a rise in anxiety and depression symptoms even in early gestation. Besides risks and pregnancy complications associated with COVID-19, mental health issues were also important.

The experience of COVID-19 pandemic should now serve for medical professionals and society in general as a model for preplanning the management of a future infection crisis.
